1. Percona XtraDB Cluster 8.0 Documentation

This documentation is for the latest release: Percona XtraDB Cluster 8.0.34-26 (Release Notes).

Percona XtraDB Cluster is a database clustering solution for MySQL. It ensures high availability, prevents downtime and data loss, and provides linear scalability for a growing environment.

1.0.1 Features of Percona XtraDB Cluster

Feature	Details
Synchronous replication	Data is written to all nodes simultaneously, or not written at all in case of a failure even on a single node
Multi-source replication	Any node can trigger a data update.
True parallel replication	Multiple threads on replica performing replication on row level
Automatic node provisioning	You simply add a node and it automatically syncs.
Data consistency	No more unsynchronized nodes.
PXC Strict Mode	Avoids the use of tech preview features and unsupported features
Configuration script for ProxySQL	Percona XtraDB Cluster includes the proxysql-admin tool that automatically configures Percona XtraDB Cluster nodes using ProxySQL.
Automatic configuration of SSL encryption	Percona XtraDB Cluster includes the pxc-encrypt-cluster-traffic variable that enables automatic configuration of SSL encryption
Optimized Performance	Percona XtraDB Cluster performance is optimized to scale with a growing production workload

Percona XtraDB Cluster 8.0 is fully compatible with MySQL Server Community Edition 8.0 and Percona Server for MySQL 8.0. The cluster has the following compatibilities:

- Data use the data created by any MySQL variant.
- Application no changes or minimal application changes are required for an application to use the cluster.

Last update: 2023-11-01

2.2 Percona XtraDB Cluster 8.0.34-26 (2023-11-01)

Percona XtraDB Cluster (PXC) supports critical business applications in your public, private, or hybrid cloud environment. Our free, open source, enterprise-grade solution includes the high availability and security features your business requires to meet your customer expectations and business goals.

2.2.1 Release highlights

Percona XtraDB Cluster is based on Percona Server for MySQL. Find a complete list of improvements and bug fixes in the Percona Server for MySQL 8.0.34-26 (2023-09-26) release notes.

Percona XtraDB Cluster implements telemetry that fills in the gaps in our understanding of how you use Percona XtraDB Cluster to improve our products. Participation in the anonymous program is optional. You can opt-out if you prefer not to share this information. Find more information in the Telemetry on Percona XtraDB Cluster document. Improvements and bug fixes introduced by Oracle for MySQL 8.0.34 and included in Percona XtraDB Cluster are the following:

- Adds mysql_binlog_open(), mysql_binlog_fetch(), and mysql_binlog_close() functions to the
 libmysqlclient.so shared library. These functions enable developers to access a MySQL server binary log.
- For platforms on which OpenSSL libraries are bundled, the linked OpenSSL library for MySQL Server is updated from OpenSSL 1.1.1 to OpenSSL 3.0.9.

Deprecations and removals

- The mysqlpump client utility program is deprecated. The use of this program causes a warning. The mysqlpump client may be removed in future releases. The applications that depend on mysqlpump will use mysqldump or MySQL Shell Utilities.
- The sync_relay_log_info server system variable is deprecated. Using this variable or its equivalent startup --sync-relay-log-info option causes a warning. This variable may be removed in future releases. The applications that use this variable should be rewritten not to depend on it before the variable is removed.
- The binlog_format server system variable is deprecated and may be removed in future releases. The functionality associated with this variable, which changes the binary logging format, is also deprecated.

When <u>binlog_format</u> is removed, MySQL server supports only row-based binary logging. Thus, new installations should use only row-based binary logging. Migrate the existing installations that use the statement-based or mixed logging format to the row-based format.

The system variables log_bin_trust_function_creators and log_statements_unsafe_for_binlog used in the context of statement-based logging are also deprecated and may be removed in future releases.

Setting or selecting the values of deprecated variables causes a warning.

- The mysql_native_password authentication plugin is deprecated and may be removed in future releases. Using CREATE USER, ALTER USER, and SET PASSWORD operations, insert a deprecation warning into the server error log if an account attempts to authenticate using mysql_native_password as an authentication method.
- The keyring_file and keyring_encrypted_file plugins are deprecated. These keyring plugins are replaced with the component_keyring_file and component_keyring_encrypted_file components.

Find the full list of bug fixes and changes in the MySQL 8.0.34 Release Notes.

2.2.2 Bug fixes

- PXC-4219: Starting a Percona XtraBackup process and issuing a START REPLICA command simultaneously could deadlock the server.
- PXC-4238: Running either the asynchronous_connection_failover_add_source user defined function or the asynchronous_connection_failover_delete_source user defined function generated an errant transaction, which could prevent a failover in the future.
- PXC-4255: Running ALTER USER/SET PASSWORD and FLUSH PRIVILEGES simultaneously on different Percona XtraDB Cluster nodes stalled the cluster.
- PXC-4284: If a MySQL user was not created before the GRANT option, the Percona XtraDB Cluster node was disconnected and needed a complete state transfer (SST).
- PXC-4288: Galera Arbitrator (garbd) used 100% CPU.
- PXC-4302: The GRANT statement could be replicated in a wrong way if partial_revokes=1 was enabled.
- PXC-4310: A warning message had an incorrect link.
- PXC-4296: The garbd 8.0.33 reported a wrong version.

Last update: 2023-11-01

2.3 Percona XtraDB Cluster 8.0.33-25 Update (2023-08-25)

Percona XtraDB Cluster (PXC) supports critical business applications in your public, private, or hybrid cloud environment. Our free, open source, enterprise-grade solution includes the high availability and security features your business requires to meet your customer expectations and business goals.

2.3.1 Known issues

If you use Galera Arbitrator (garbd), we recommend that you do not upgrade to 8.0.33 because garbd-8.0.33 may cause synchronization issues and extensive usage of CPU resources.

If you already upgraded to garbd-8.0.33, we recommended downgrading to garbd-8.0.32-24-2 by performing the following steps:

- Uninstall the percona-xtradb-cluster-garbd_8.0.33-25 package.
- Download the percona-xtradb-cluster-garbd_8.0.32-24-2 package from Percona Software Downloads manually.
- Install the percona-xtradb-cluster-garbd_8.0.32-24-2 package manually.

Last update: 2023-08-25

2.4 Percona XtraDB Cluster 8.0.33-25 (2023-08-02)

Percona XtraDB Cluster (PXC) supports critical business applications in your public, private, or hybrid cloud environment. Our free, open source, enterprise-grade solution includes the high availability and security features your business requires to meet your customer expectations and business goals.

2.4.1 Release highlights

Percona XtraDB Cluster is based on Percona Server for MySQL. Find a complete list of improvements and bug fixes in the Percona Server for MySQL 8.0.33-25 (2023-06-15) release notes.

Improvements and bug fixes introduced by Oracle for MySQL 8.0.33 and included in Percona XtraDB Cluster are the following:

- The INSTALL COMPONENT includes the SET clause. The SET clause sets the values of component system variables when installing one or several components. This reduces the inconvenience and limitations associated with assigning variable values in other ways.
- The mysqlbinlog --start-position accepts values up to 18446744073709551615. If the --read-from-remoteserver or --read-from-remote-source option is used, the maximum is 4294967295. (Bug #77818, Bug #21498994)
- Using a generated column with DEFAULT(col_name) to specify the default value for a named column is not allowed and throws an error message. (Bug #34463652, Bug #34369580)
- Not all possible error states were reported during the binary log recovery process. (Bug #33658850)
- User-defined collations are deprecated. The usage of the following user-defined collations causes a warning that is written to the log:
- When COLLATE is followed by the name of a user-defined collation in an SQL statement.
- When the name of a user-defined collation is used as the value of collation_server, collation_database, or collation_connection.

The support for user-defined collations will be removed in a future releases of MySQL.

Find the full list of bug fixes and changes in the MySQL 8.0.33 Release Notes.

2.4.2 New features

• PXC-3760: Added FC auto eviction variables allow the eviction of a lagging node.

2.4.3 Bug fixes

- PXC-667: Unexpected exit during the BF-abort of active HANDLER OPEN AS <alias>.
- PXC-679: An undetected state gap discovery causes the server to hang on shutdown.
- PXC-4222: When a node abruptly leaves the applier thread causes all the other nodes in the cluster to hang.
- PXC-4225: In the INFORMATION_SCHEMA.PROCCESSLIST, the COMMAND value is incorrect.
- PXC-4228: The NBO mode corrupted the binary log.
- PXC-4233: A cluster state interruption during NBO can lead to a permanent cluster lock.
- PXC-4253: The merge to 8.0.33 fixes a number of CVE vulnerabilities.
- PXC-4258: A failure to add a foreign key resulted in an inconsistency.
- PXC-4268: If the ALTER DEFINER VIEW was changed with insufficient privileges, the Percona XtraDB Cluster node gets a Disconnected/Inconsistent state
- PXC-4278: Renaming a table with NBO caused a server exit.

2.5 Percona XtraDB Cluster 8.0.32-24.2 (2023-05-24)

Release date	May 24, 2023	
Install instructions	Install Percona XtraDB Cluster	

Percona XtraDB Cluster (PXC) supports critical business applications in your public, private, or hybrid cloud environment. Our free, open source, enterprise-grade solution includes the high availability and security features your business requires to meet your customer expectations and business goals.

2.5.1 Release highlights

This release of Percona XtraDB Cluster 8.0.32-24 includes the fix for PXC-4211.

2.5.2 Bug fixes

- PXC-4211: The server exited on the binary log rotation.
- PXC-4217: The cluster can intermittently abort a node on an insert query.
- PXC-4222: A node abruptly leaving the cluster causes the applier thread to hang on all the remaining nodes.

Last update: 2023-05-18

2.6 Percona XtraDB Cluster 8.0.32-24 (2023-04-18)

Release date		April 18, 2023	
	Install instructions	Install Percona XtraDB Cluster	

Percona XtraDB Cluster (PXC) supports critical business applications in your public, private, or hybrid cloud environment. Our free, open source, enterprise-grade solution includes the high availability and security features your business requires to meet your customer expectations and business goals.

2.6.1 Release highlights

Percona XtraDB Cluster is based on Percona Server for MySQL. Find a complete list of improvements and bug fixes in the Percona Server for MySQL 8.0.32-24 (2023-03-20) release notes.

Percona decided to revert the following MySQL bug fix:

The data and the GTIDs backed up by mysqldump were inconsistent when the options --single-transaction and --set-gtid-purged=0N were both used. It was because in between the transaction started by mysqldump and the fetching of GTID_EXECUTED, GTIDs on the server could have increased already. With this fixed, a FLUSH TABLES WITH READ LOCK is performed before the fetching of GTID_EXECUTED to ensure its value is consistent with the snapshot taken by mysqldump.

The MySQL fix also added a requirement when using -single-transaction and executing FLUSH TABLES WITH READ LOCK for the RELOAD privilege. (MySQL bug #109701, MySQL bug #105761)

The Percona Server version of the mysqldump utility, in some modes, can be used with MySQL Server. This utility provides a temporary workaround for the "additional RELOAD privilege" limitation introduced by Oracle MySQL Server 8.0.32.

For more information, see the Percona Performance Blog A Workaround for the "RELOAD/FLUSH_TABLES privilege required" Problem When Using Oracle mysqldump 8.0.32.

Improvements and bug fixes introduced by Oracle for MySQL 8.0.32 and included in Percona Server for MySQL are the following:

- A replica can add a Generated Invisible Primary Keys(GIPK) to any InnoDB table. To achieve this behavior, the GENERATE value is added as a possible value for the CHANGE REPLICATION SOURCE TO statement's REQUIRE_TABLE_PRIMARY_KEY_CHECK option.
- The REQUIRE_TABLE_PRIMARY_KEY_CHECK = GENERATE option can be used on a per-channel basis.
- Setting sql_generate_invisible_primary_key on the source is ignored by a replica because this variable is not replicated. This behavior is inherited from the previous releases.
- An upgrade from 8.0.28 caused undetectable problems, such as server exit and corruption.
- A fix for after an upgrade, all columns added with ALGORITHM=INSTANT materialized and have version=0 for any new row inserted. Now, a column added with ALGORITHM=INSTANT fails if the maximum possible size of a row exceeds the row size limit, so that all new rows with materialized ALGORITHM=INSTANT columns are within row size limit. (Bug #34558510)
- After a drop, adding a specific column using the INSTANT algorithm could cause a data error and a server exit. (Bug #34122122)
- An online rebuild DDL no longer crashes after a column is added with ALGORITHM=INSTANT. Thank you Qingda Hu for reporting this bug. (Bug #33788578, Bug #106279)

2.6.2 Bug fixes

- PXC-3936: State transfer with disabled SSL in wsrep_provider_options option crashed the Receiver and Donor nodes.
- PXC-3976: The wsrep status vars were not updated when 8.0 node joined the 5.7 cluster.
- PXC-4137: The WSREP applier threads failed to modify read-only schemas.
- PXC-4162: When doing a rolling upgrade from 5.7 to 8.0, wsrep_cluster_size was 0.
- PXC-4163: The pxc_strict_mode option did not detect version mismatch.

2.8 Percona XtraDB Cluster 8.0.31-23 (2023-03-14)

Release date	2023-11-01	
Install instructions	Install Percona XtraDB Cluster	

Percona XtraDB Cluster (PXC) supports critical business applications in your public, private, or hybrid cloud environment. Our free, open source, enterprise-grade solution includes the high availability and security features your business requires to meet your customer expectations and business goals.

2.8.1 Release highlights

Percona XtraDB Cluster is based on Percona Server for MySQL. Find a complete list of improvements and bug fixes in the Percona Server for MySQL 8.0.31-23 (2022-11-21) release notes.

This release adds the following feature in tech preview:

GCache encryption and Write-Set cache encryption

Improvements and bug fixes introduced by Oracle for MySQL 8.0.31 and included in Percona Server for MySQL are the following:

- MySQL adds support for the SQL standard INTERSECT and EXCEPT table operators.
- InnoDB supports parallel index builds. This improves index build performance. The sorted index entries are loaded into a B-tree in a multithread. In previous releases, this action was performed by a single thread.
- The Performance and sys schemas show metrics for the global and session memory limits introduced in MySQL 8.0.28.

The following columns have been added to the Performance Schema tables:

Performance Schema tables	Columns
SETUP_INSTRUMENTS	FLAGS
THREADS	CONTROLLED_MEMORY, MAX_CONTROLLED_MEMORY, TOTAL_MEMORY, MAX_TOTAL_MEMORY
EVENTS_STATEMENTS_CURRENT, EVENTS_STATEMENTS_HISTORY, EVENTS_STATEMENTS_HISTORY_LONG	MAX_CONTROLLED_MEMORY, MAX_TOTAL_MEMORY
Statement Summary Tables	MAX_CONTROLLED_MEMORY, MAX_TOTAL_MEMORY
Performance Schema Connection Tables	MAX_SESSION_CONTROLLED_MEMORY, MAX_SESSION_TOTAL_MEMORY
PREPARED_STATEMENTS_INSTANCES	MAX_CONTROLLED_MEMORY, MAX_TOTAL_MEMORY

The following columns have been added to the sys schema STATEMENT_ANALYSIS and X\$STATEMENT_ANALYSIS views:

MAX_CONTROLLED_MEMORY

MAX_TOTAL_MEMORY

The controlled_by_default flag has been added to the PROPERTIES column of the SETUP_INSTRUMENTS table. Now, you can add and remove non-global memory instruments to the set of controlled-memory

SQL> UPDATE PERFORMANCE_SCHEMA.SETUP_INTRUMENTS SET FLAGS="controlled"
WHERE NAME='memory/sql/NET::buff';

instruments. To do this, set the value of the FLAGS column of SETUP_INSTRUMENTS.

• The audit_log_flush variable has been deprecated and will be removed in future releases.

Find the full list of bug fixes and changes in the MySQL 8.0.31 Release Notes.

2.8.2 New Features

- Added support for GCache and Write-Set encryption.
- PXC-3574: Added support for the wsrep_mode variable.

2.8.3 Improvement

• The Data at Rest encryption now encrypts Record-Set cache.

2.8.4 Bug fixes

- PXC-3989: Added support for keyring components.
- PXC-4077: Injecting an empty transaction caused GTID inconsistencies between nodes.
- PXC-4120: Enabling wsrep-debug created multiple entries of wsrep commit empty() in the Error log.
- PXC-4126: When stream replication and TOI are active, the CREATE USER statement was not allowed.
- PXC-4116: A PXC replica node stalled with parallel asynchronous parallel replication.
- PXC-4148: A fix for the MDL conflict db= ticket=10 solved by abort error.

2.9.1 Release highlights

Percona XtraDB Cluster is based on Percona Server for MySQL. Find a complete list of improvements and bug fixes in the Percona Server for MySQL 8.0.30-22 (2022-11-21) release notes.

🧪 Note

The following Percona Server for MySQL 8.0.30 features are not supported in this version of Percona XtraDB Cluster:

- Amazon Key Management Service
- Key Management Interoperability Protocol

The features will be supported in the next version of Percona XtraDB Cluster.

Improvements and bug fixes introduced by Oracle for *MySQL* 8.0.30 and included in *Percona Server for MySQL* are the following:

- Supports Generated Invisible Primary Keys(GIPK). This feature automatically adds a primary key to InnoDB tables without a primary key. The generated key is always named <code>my_row_id</code>. The GIPK feature is not enabled by default. Enable the feature by setting <code>sql_generate_invisible primary key</code> to ON.
- The InnoDB_doublewrite system has two new settings:
- DETECT_ONLY. This setting allows only metadata to be written to the doublewrite buffer. Database page content is not written to the buffer. Recovery does not use the buffer to fix incomplete page writes. Use this setting only when you need to detect incomplete page writes.
- DETECT_AND_RECOVER. This setting is equivalent to the current ON setting. The doublewrite buffer is enabled. Database page content is written to the buffer and the buffer is accessed to fix incomplete page writes during recovery.
- The -skip_host_cache server option is deprecated and will be removed in a future release. Use SET GLOBAL host_cache_size = 0 or set host_cache_size = 0.

Find the full list of bug fixes and changes in the MySQL 8.0.30 release notes.

2.9.2 Bug fixes

- PXC-3639: The buffer overflow was not considered when using strncpy in WSREP patch.
- PXC-3821: The truncation of the performance_schema table on a node was replicated across the cluster.
- PXC-4012: The replica node left the cluster when executing CREATE USER with password_history option simultaneously.
- PXC-4033: When the prepared statement is executed in parallel to the DDL modifying the table that the prepared statement uses, the server fails with an assertion saying that the prepared statement transaction was aborted, so it cannot be committed.
- PXC-4048: gra_x_y_v2.log files created in case of failures were empty.

2.9.3 Platform support

- Percona XtraDB Cluster 8.0.30-22 supports Oracle Linux/Red Hat Enterprise Linux 9.
- Percona XtraDB Cluster 8.0.30-22 supports Ubuntu 22.04.

Last update: 2022-12-28

2.10 Percona XtraDB Cluster 8.0.29-21 (2022-09-12)

Percona XtraDB Cluster (PXC) supports critical business applications in your public, private, or hybrid cloud environment. Our free, open source, enterprise-grade solution includes the high availability and security features your business requires to meet your customer expectations and business goals.

2.10.1 Release Highlights

Percona XtraDB Cluster is based on Percona Server for MySQL. Find a complete list of improvements and bug fixes in the Percona Server for MySQL 8.0.29-21 (2022-08-08) release notes.

The improvements and bug fixes for MySQL 8.0.29, provided by Oracle, and included in Percona Server for MySQL are the following:

The Performance Schema tracks if a query was processed on the PRIMARY engine, InnoDB, or a SECONDARY engine, HeatWave. An EXECUTION_ENGINE column, which indicates the engine used, was added to the Performance Schema statement event tables and the sys.processlist and the sys.x\$processlist views.

Added support for the IF NOT EXISTS option for the CREATE FUNCTION, CREATE PROCEDURE, and CREATE TRIGGER statements.

Added support for ALTER TABLE ... DROP COLUMN ALGORITHM=INSTANT.

An anonymous user with the PROCESS privilege was unable to select processlist table rows.

Find the full list of bug fixes and changes in the MySQL 8.0.29 Release Notes.

Percona Server for MySQL has changed the default for the supported DDL column operations to ALGORITHM=INPLACE. This change fixes the corruption issue with the INSTANT ADD/DROP COLUMNS (find more details in PS-8292.

In MySQL 8.0.29, the default setting for supported DDL operations is ALGORITHM=INSTANT. You can explicitly specify ALGORITHM=INSTANT in DDL column operations.

2.10.2 Bugs Fixed

- PXC-3982: When the replica node is also an asynchronous slave and, while joining the cluster, this node was not ready to accept connections, a SQL thread failed at the start.
- PXC-3118: A fix for when, using a thread pool, a brute force abort for a metadata locking (MDL) subsystem conflict stalled.
- PXC-3999: The cluster was stalled on Waiting for acl cache lock with concurrent user DDL commands.

2.10.3 Packaging Notes

Debian 9 is no longer supported.

Last update: 2023-07-21

2.11 Percona XtraDB Cluster 8.0.28-19.1 (2022-07-19)

Percona XtraDB Cluster (PXC) supports critical business applications in your public, private, or hybrid cloud environment. Our free, open source, enterprise-grade solution includes the high availability and security features your business requires to meet your customer expectations and business goals.

2.11.1 Release Highlights

Improvements and bug fixes introduced by Oracle for *MySQL* 8.0.28 and included in Percona Server for MySQL are the following:

- The ASCII shortcut for CHARACTER SET latin1 and UNICODE shortcut for CHARACTER SET ucs2 are deprecated and raise a warning to use CHARACTER SET instead. The shortcuts will be removed in a future version.
- A stored function and a loadable function with the same name can share the same namespace. Add the schema name when invoking a stored function in the shared namespace. The server generates a warning when function names collide.
- InnoDB supports ALTER TABLE ... RENAME COLUMN operations when using ALGORITHM=INSTANT.
- The limit for innodb_open_files now includes temporary tablespace files. The temporary tablespace files were not counted in the innodb_open_files in previous versions.

Find the full list of bug fixes and changes in the MySQL 8.0.28 Release Notes.

2.11.2 Bugs Fixed

- PXC-3923: When the read_only or super_read_only option was set, the ANALYZE TABLE command removed the node from the cluster.
- PXC-3388: Percona XtraDB Cluster stuck in a DESYNCED state after joiner was killed.
- PXC-3609: The binary log status variables were updated when the binary log was disabled. Now the status variables are not registered when the binary log is disabled. (Thanks to Stofa Kenida for reporting this issue.)
- PXC-3848: The cluster node exited when the CURRENT_USER() function was used. (Thanks to Steffen Böhme for reporting this issue.)
- PXC-3872: A user without system_user privilege was able to drop system users. (Thanks to user jackc for reporting this issue.)
- PXC-3918: Galera Arbitrator (garbd) could not connect if the Percona XtraDB Cluster server used encrypted connections. The issue persisted even when the proper certificates were specified.
- PXC-3924: Using TRUNCATE TABLE X and INSERT INTO X options when the foreign keys were disabled and violated caused the HA_ERR_FOUND_DUPP_KEY error on a slave node. (Thanks to Daniel Bartoníček for reporting this issue.)
- PXC-3062: The wsrep_incoming_addresses status variable did not contain the garbd IP address.

Last update: 2023-07-21

2.12 Percona XtraDB Cluster 8.0.27-18.1

Date: April 11, 2022

Percona XtraDB Cluster (PXC) supports critical business applications in your public, private, or hybrid cloud environment. Our free, open source, enterprise-grade solution includes the high availability and security features your business requires to meet your customer expectations and business goals.

2.12.1 Release Highlights

The following lists a number of the bug fixes for *MySQL* 8.0.27, provided by Oracle, and included in Percona Server for MySQL:

- The default_authentication_plugin is deprecated. Support for this plugin may be removed in future versions. Use the authentication_policy variable.
- The binary operator is deprecated. Support for this operator may be removed in future versions. Use CAST(... AS BINARY).
- Fix for when a parent table initiates a cascading SET NULL operation on the child table, the virtual column can be set to NULL instead of the value derived from the parent table.

Find the full list of bug fixes and changes in the MySQL 8.0.27 Release Notes.

2.12.2 Bugs Fixed

- PXC-3831: Allowed certified high-priority transactions to proceed without lock conflicts.
- PXC-3766: Stopped every XtraBackup-based SST operation from executing the version-check procedure.
- PXC-3704: Based the maximum writeset size on repl.max_ws_size when both repl.max_ws_size and wsrep_max_ws_size values are passed during startup.

2.12.3 Useful Links

Last update: 2023-07-21

2.13 Percona XtraDB Cluster 8.0.26-16.1

• Date

January 17, 2022

Installation

Installing Percona XtraDB Cluster

Percona XtraDB Cluster (PXC) supports critical business applications in your public, private, or hybrid cloud environment. Our free, open source, enterprise-grade solution includes the high availability and security features your business requires to meet your customer expectations and business goals.

2.13.1 Release Highlights

The following are a number of the notable fixes for MySQL 8.0.26, provided by Oracle, and included in this release:

- The TLSv1 and TLSv1.1 connection protocols are deprecated.
- Identifiers with specific terms, such as "master" or "slave" are deprecated and replaced. See the Functionality Added or Changed section in the 8.0.26 Release Notes for a list of updated identifiers. The following terms have been changed:
- The identifier master is changed to source
- The identifier slave is changed to replica
- The identifier multithreaded slave (mts) is changed to multithreaded applier (mta)
- When using semisynchronous replication, either the old version or the new version of system variables and status variables are available. You cannot have both versions installed on an instance. The old system variables are available when you use the old version, but the new ones are not. The new system variables are available when you use the new version, but the old values are not.

In an upgrade from an earlier version to 8.0.26, enable the rpl_semi_sync_source plugin and the rpl_semi_sync_replica plugin after the upgrade has been completed. Enabling these plugins before all of the nodes are upgraded may cause data inconsistency between the nodes.

For the source, the <code>rpl_semi_sync_master</code> plugin (<code>seminsync_master.so</code> library) is the old version and the <code>rpl_semi_sync_source</code> plugin(<code>semisync_source.so</code> library) is the new version.

For the client, the <code>rpl_semi_sync_slave</code> plugin (<code>semisync_slave.so</code> library) is the old version and the <code>rpl_semi_sync_replica</code> plugin (<code>semisync_replica.so</code> library) is the new version

For more information, see the MySQL 8.0.26 Release Notes.

2.13.2 Bugs Fixed

- PXC-3824: An incorrect directive in Systemd Unit File (Thanks to Jim Lohiser for reporting this issue)
- PXC-3706: A fix for a race condition in group commit queue (Thanks to Kevin Sauter for reporting this issue)
- PXC-3739: The FLUSH TABLES FOR EXPORT lock is released when the session ends.
- PXC-3628: The server allowed altering the storage engine to MyISAM for mysql.wsrep_* tables.
- PXC-3731: A fix for when the user deletes data from the source but does not want that data deleted from the replica. The sql_log_bin=0 command had no effect and the deleted rows were replicated and written into the binary log.
- PXC-3857: The following system variables are renamed. The old variables are deprecated and may be removed in a future version.
- wsrep_slave_threads renamed as wsrep_applier_threads
- wsrep_slave_FK_checks renamed as wsrep_applier_FK_checks
- wsrep_slave_UK_checks renamed as wsrep_applier_UK_checks
- wsrep_restart_slave renamed as wsrep_restart_replica

2.13.3 Known Issues (unfixed problems that you should be aware of)

- PXC-3039: No useful error messages if an SSL-disabled node tried to join an SSL-enabled cluster
- PXC-3093: A completed SST Transfer is incorrectly logged by garbd. The timing is incorrect.

Last update: 2023-01-20

2.14 Percona XtraDB Cluster 8.0.25-15.1

• Date

November 22, 2021

Installation

Installing Percona XtraDB Cluster.

Percona XtraDB Cluster 8.0.25-15.1 includes all of the features and bug fixes available in Percona Server for MySQL. See the corresponding release notes for Percona Server for MySQL 8.0.25-15 for more details on these changes.

Percona XtraDB Cluster (PXC) supports critical business applications in your public, private, or hybrid cloud environment. Our free, open source, enterprise-grade solution includes the high availability and security features your business requires to meet your customer expectations and business goals.

2.14.1 Release Highlights

A Non-Blocking Operation method for online schema changes in Percona XtraDB Cluster. This mode is similar to the Total Order Isolation (TOI) mode, whereas a data definition language (DDL) statement (for example, ALTER) is executed on all nodes in sync. The difference is that in the NBO mode, the DDL statement acquires a metadata lock that locks the table or schema at a late stage of the operation, which is a more efficient locking strategy.

Note that the NBO mode is a **Tech Preview** feature. We do not recommend that you use this mode in a production environment. For more information, see Non-Blocking Operations (NBO) method for Online Scheme Upgrades (OSU).

The notable changes and bug fixes introduced by Oracle MySQL include the following:

- The sql slave skip counter variable only counts the events in the uncompressed transaction payloads.
- A possible deadlock occurred when system variables, read by different clients, were being updated and the binary log file was rotated.
- Sometimes the aggregate function results could return values from a previous statement when using a prepared SELECT statement with a WHERE clause that is always false.

For more information, see the MySQL 8.0.24 Release Notes and the MySQL 8.0.25 Release Notes.

2.14.2 New Features

• PXC-3265 Implements the Non-Blocking Operations (NBO) mode for an Online schema upgrade.

2.14.3 Bugs Fixed

- PXC-3275: Fix the documented APT package list to match the packages listed in the Repo. (Thanks to user Hubertus Krogmann for reporting this issue)
- PXC-3387: Performing an intermediate commit does not call wsrep commit hooks.
- PXC-3449: Fix for missing dependencies which were carried out in replication writesets caused Galera to fail.
- PXC-3589: Documentation: Updates in Percona XtraDB Cluster Limitations that the LOCK=NONE clause is no longer allowed in an INPLACE ALTER TABLE statement. (Thanks to user Brendan Byrd for reporting this issue)
- PXC-3611: Fix that deletes any keyring backup file if it exists for SST operation.
- PXC-3608: Fix a concurrency issue that caused a server exit when attempting to read a foreign key.
- PXC-3637: Changes the service start sequence to allow more time for mounting local or remote directories with large amounts of data. (Thanks to user Eric Gonyea for reporting this issue)
- PXC-3679: Fix for SST failures after the update of socat to '1.7.4.0'.
- PXC-3706: Fix adds a wait to wsrep_after_commit until the first thread in a group commit queue is available.
- PXC-3729: Fix for conflicts when multiple applier threads execute certified transactions and are in High-Priority transaction mode.
- PXC-3731: Fix for incorrect writes to the binary log when sql_log_bin=0.
- PXC-3733: Fix to clean the WSREP transaction state if a transaction is requested to be re-prepared.

Last update: 2023-07-21

2.15 Percona XtraDB Cluster 8.0.23-14.1

• Date

June 9, 2021

Installation

Installing Percona XtraDB Cluster.

Percona XtraDB Cluster 8.0.23-14.1 includes all of the features and bug fixes available in Percona Server for MySQL. See the corresponding release notes for Percona Server for MySQL 8.0.23-14 for more details on these changes.

2.15.1 Improvements

• PXC-3092: Log a warning at startup if a keyring is specified, but the cluster traffic encryption is turned off

2.15.2 Bugs Fixed

- PXC-3464: Data is not propagated with SET SESSION sql_log_bin = 0
- PXC-3146: Galera/SST is not looking for the default data directory location for SSL certs
- PXC-3226: Results from CHECK TABLE from PXC server can cause the client libraries to crash
- PXC-3381: Modify GTID functions to use a different char set
- PXC-3437: Node fails to join in the endless loop
- PXC-3446: Memory leak during server shutdown

- PXC-3538: Garbd crashes after successful backup
- PXC-3580: Aggressive network outages on one node makes the whole cluster unusable
- PXC-3596: Node stuck in aborting SST
- PXC-3645: Deadlock during ongoing transaction and RSU

Last update: 2022-08-24

2.16 Percona XtraDB Cluster 8.0.22-13.1

• Date

March 22, 2021

Installation

Installing Percona XtraDB Cluster

Percona XtraDB Cluster 8.0.22–13.1 includes all of the features and bug fixes available in Percona Server for MySQL. See the corresponding release notes for Percona Server for MySQL 8.0.22–13 for more details on these changes.

This release fixes security vulnerability CVE-2021-27928, a similar issue to CVE-2020-15180

2.16.1 Improvements

- PXC-3575: Implement package changes for SELinux and AppArmor
- PXC-3115: Create Default SELinux and AppArmor policy

2.16.2 Bugs Fixed

- PXC-3536: Modify processing to not allow threads/queries to be killed if the thread is in TOI
- PXC-3565: Correct Performance of SELECT in PXC
- PXC-3502: Correct condition in thd_binlog_format() function for List Index process (Thanks to user Paweł Bromboszcz for reporting this issue)
- PXC-3501: Modify wsrep_row_upd_check_foreign_constraints() to include foreign key dependencies in the writesets for DELETE query (Thanks to user Steven Gales for reporting this issue)
- PXC-2913: Correct MDL locks assertion when wsrep provider is unloaded
- PXC-3475: Adjust mysqld_safe script to parse 8.0 log style properly

2.16.3 Known Issues (unfixed problems that you should be aware of)

- PXC-3039: No useful error messages if an SSL-disabled node tries to join an SSL-enabled cluster
- PXC-3092: Log a warning at startup if a keyring is specified, but cluster traffic encryption is turned off
- PXC-3093: Completed SST Transfer incorrectly logged by garbd (Timing is not correct)

Last update: 2022-08-24

2.17 Percona XtraDB Cluster 8.0.21-12.1

• Date

December 28, 2020

Installation

Installing Percona XtraDB Cluster

Percona XtraDB Cluster 8.0.21-12.1 includes all of the features and bug fixes available in Percona Server for MySQL. See the corresponding release notes for Percona Server for MySQL 8.0.21-12 for more details on these changes.

Implement an inconsistency voting policy. In the best case scenario, the node with the inconsistent data is aborted and the cluster continues to operate.

2.17.1 Improvements

• PXC-2574: Improve messaging for "BF lock wait long" timeout

2.17.2 Bugs Fixed

- PXC-3353: Modify error handling in Garbd when donor crashes during SST or when an invalid donor name is passed to it
- PXC-3468: Resolve package conflict when installing PXC 5.7 on RHEL/CentOS8
- PXC-3418: Prevent DDL-DML deadlock by making in-place ALTER take shared MDL for the whole duration.
- PXC-3416: Fix memory leaks in garbd when started with invalid group name
- PXC-3445: Correct MTR test failures
- PXC-3442: Fix crash when log_slave_updates=ON and consistency check statement is executed
- PXC-3424: Fix error handling when the donor is not able to serve SST
- PXC-3404: Fix memory leak in garbd while processing CC actions
- PXC-3191: Modify Read-Only checks on wsrep_* tables when in super_read_only

2.17.3 Known Issues (unfixed problems that you should be aware of)

- PXC-3039: No useful error messages if an SSL-disabled node tries to join an SSL-enabled cluster
- PXC-3092: Log a warning at startup if a keyring is specified but cluster traffic encryption is turned off
- PXC-3093: Completed SST Transfer incorrectly logged by garbd (Timing is not correct)
- PXC-3159: Modify the error handling to close the communication channels and abort the joiner node when the donor crashes

Last update: 2022-08-24

2.18 Percona XtraDB Cluster 8.0.20-11

• Date

October 1, 2020

Installation

Installing Percona XtraDB Cluster

Percona XtraDB Cluster 8.0.20-11 includes all of the features and bug fixes available in Percona Server for MySQL. See the corresponding release notes for Percona Server for MySQL 8.0.20-11 for more details on these changes.

2.18.1 Improvements

• PXC-2603: Update Index for PXC status variables - apply consistent definitions

2.18.2 Bugs Fixed

- PXC-3159: Modify error handling to close the communication channels and abort the joiner node when donor crashes (previously was Known Issue)
- PXC-3352: Modify wsrep_row_upd_check_foreign_constraints() to remove the check for DELETE
- PXC-3371: Fix Directory creation in build-binary.sh
- PXC-3370: Provide binary tarball with shared libs and glibc suffix & minimal tarballs
- PXC-3360: Update sysbench commands in PXC-ProxySQL configuration doc page
- PXC-3312: Prevent cleanup of statement diagnostic area in case of transaction replay.
- PXC-3167: Correct GCache buffer repossession processing
- PXC-3347: Modify PERCONA_SERVER_EXTENSION for bintarball and modify MYSQL_SERVER_SUFFIX

2.18.3 Known Issues (unfixed problems that you should be aware of)

- PXC-3039: No useful error messages if an SSL-disabled node tries to join SSL-enabled cluster
- PXC-3092: Log warning at startup if keyring is specified but cluster traffic encryption is turned off
- PXC-3093: Garbd logs Completed SST Transfer Incorrectly (Timing is not correct)

Last update: 2022-08-24

2.19 Percona XtraDB Cluster 8.0.20-11.3

• Date

October 22, 2020

Installation

Installing Percona XtraDB Cluster

2.19.1 Bugs Fixed

• PXC-3456: Allow specific characters in SST method names and SST request data.

Last update: 2022-08-24

2.20 Percona XtraDB Cluster 8.0.20-11.2

• Date

October 9, 2020

Installation

Installing Percona XtraDB Cluster

This release fixes the security vulnerability CVE-2020-15180

Last update: 2022-08-24

2.21 Percona XtraDB Cluster 8.0.19-10

• Date

June 18, 2020

Installation

Installing Percona XtraDB Cluster

Percona XtraDB Cluster 8.0.19-10 includes all of the features and bug fixes available in Percona Server for MySQL. See the corresponding release notes for Percona Server for MySQL 8.0.19-10 for more details on these changes.

2.21.1 Improvements

- PXC-2189: Modify Reference Architecture for Percona XtraDB Cluster (PXC) to include ProxySQL
- PXC-3182: Modify processing to not allow writes on 8.0 nodes while 5.7 nodes are still on the cluster
- PXC-3187: Add dependency package installation note in PXC binary tarball installation doc.
- PXC-3138: Document mixed cluster write (PXC8 while PXC5.7 nodes are still part of the cluster) should not be completed.
- PXC-3066: Document that pxc-encrypt-cluster-traffic=OFF is not just about traffic encryption
- PXC-2993: Document the dangers of running with strict mode disabled and Group Replication at the same time
- PXC-2980: Modify Documentation to include AutoStart Up Process after Installation
- PXC-2604: Modify garbd processing to support Operator

2.21.2 Bugs Fixed

- PXC-3298: Correct galera_var_reject_queries test to remove display value width
- PXC-3320: Correction on PXC installation doc
- PXC-3270: Modify wsrep_ignore_apply_errors variable default to restore 5.x behavior
- PXC-3179: Correct replication of CREATE USER ... RANDOM PASSWORD
- PXC-3080: Modify to process the ROTATE_LOG_EVENT synchronously to perform proper cleanup
- PXC-2935: Remove incorrect assertion when -thread_handling=pool-of-threads is used
- PXC-2500: Modify ALTER USER processing when executing thread is Galera applier thread to correct assertion

- PXC-3234: Correct documentation link in spec file
- PXC-3204: Modify to set wsrep_protocol_version correctly when wsrep_auto_increment_control is disabled
- PXC-3189: Correct SST processing for super_read_only
- PXC-3184: Modify startup to correct crash when socat not found and SST Fails
- PXC-3169: Modify wsrep_reject_queries to enhance error messaging
- PXC-3165: Allow COM_FIELD_LIST to be executed when WSREP is not ready
- PXC-3145: Modify to end mysqld process when the joiner fails during an SST
- PXC-3043: Update required donor version to PXC 5.7.28 (previously was Known Issue)
- PXC-3036: Document correct method for starting, stopping, bootstrapping
- PXC-3287: Correct link displayed on help client command
- PXC-3031: Modify processing for garbd to prevent issues when multiple requests are started at approximately the same time and request an SST transfers to prevent SST from hanging

2.21.3 Known Issues

- PXC-3039: No useful error messages if an SSL-disabled node tries to join SSL-enabled cluster
- PXC-3092: Abort startup if keyring is specified but cluster traffic encryption is turned off
- PXC-3093: Garbd logs Completed SST Transfer Incorrectly (Timing is not correct)
- PXC-3159: Killing the Donor or Connection lost during SST Process Leaves Joiner Hanging

Last update: 2022-08-24

2.22 Percona XtraDB Cluster 8.0.18-9.3

• Date

April 29, 2020

Installation

Installing Percona XtraDB Cluster

Percona XtraDB Cluster 8.0.18–9.3 includes all of the features and bug fixes available in Percona Server for MySQL. See the corresponding release notes for Percona Server for MySQL 8.0.18–9 for more details on these changes.

2.22.1 Improvements

- PXC-2495: Modified documentation for wsrep_sst_donor to include results when IP address is used
- PXC-3002: Enhanced service_startup_timeout options to allow it to be disabled
- PXC-2331: Modified the SST process to run mysql_upgrade
- PXC-2991: Enhanced Strict Mode Processing to handle Group Replication Plugin
- PXC-2985: Enabled Service for Automated Startup on Reboot with valid grastate.dat
- PXC-2980: Modified Documentation to include AutoStart Up Process after Installation
- PXC-2722: Enabled Support for Percona XtraBackup (PXB) 8.0.8 in Percona XtraDB Cluster (PXC) 8.0
- PXC-2602: Added Ability to Configure xbstream options with wsrep_sst_xtrabackup

- PXC-2455: Implemented the use of Percona XtraBackup (PXB) 8.0.5 in Percona XtraDB Cluster (PXC) 8.0
- PXC-2259: Updated wsrep-files-index.htrml to include new files created by Percona XtraDB Cluster (PXC)
- PXC-2197: Modified SST Documentation to Include Package Dependencies for Percona XtraBackup (PXB)
- PXC-2194: Improvements to the PXC upgrade guide
- PXC-2191: Revised Documentation on innodb_deadlock to Clarify Cluster Level Deadlock Processing
- PXC-3017: Remove these SST encryption methods. encrypt=1, encrypt=2, and encrypt=3
- PXC-2189: Modified Reference Architecture for Percona XtraDB Cluster (PXC) to include ProxySQL

2.22.2 Bugs Fixed

- PXC-2537: Modified mysqladmin password command to prevent node crash
- PXC-2958: Modified User Documentation to include wsrep_certification_rules and cert.optimistic_pa
- PXC-2045: Removed debian.cnf reference from logrotate/logcheck configuration Installed on Xenial/ Stretch
- PXC-2292: Modified Processing to determine Type of Key Cert when IST/SST
- PXC-2974: Modified Percona XtraDB Cluster (PXC) Dockerfile to Integrate Galera wsrep recovery Process
- PXC-3145: When the joiner fails during an SST, the mysqld process stays around (doesn't exit)
- PXC-3128: Removed Prior Commit to Allow High Priority High Transaction Processing
- PXC-3076: Modified Galera build to remove python3 components
- PXC-2912: Modified netcat Configuration to Include -N Flag on Donor
- PXC-2476: Modified process to determine and process IST or SST and with keyring_file processing
- PXC-2204: Modified Shutdown using systemd after Bootstrap to provide additional messaging
- PXB-2142: Transition key was written to backup / stream
- PXC-2969: Modified pxc_maint_transition_period Documentation to Include Criteria for Use

2.22.3 Known Issues

- PXC-2978: Certificate Information not Displayed when pxc-encrypt-cluster-traffic=ON
- PXC-3039: No useful error messages if an SSL-disabled node tries to join SSL-enabled cluster
- PXC-3043: Update required donor version to PXC 5.7.28
- PXC-3063: Data at Rest Encryption not Encrypting Record Set Cache
- PXC-3092: Abort startup if keyring is specified but cluster traffic encryption is turned off
- PXC-3093: Garbd logs Completed SST Transfer Incorrectly (Timing is not correct)
- PXC-3159: Killing the Donor or Connection lost during SST Process Leaves Joiner Hanging

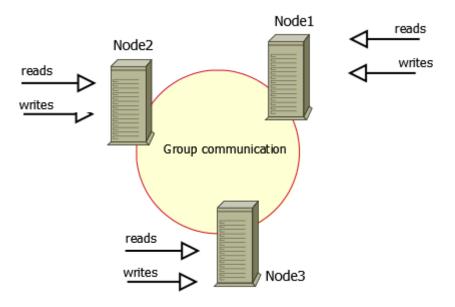

Last update: 2022-08-24

3. Introduction

3.1 About Percona XtraDB Cluster

Percona XtraDB Cluster is a fully open-source high-availability solution for MySQL. It integrates Percona Server for MySQL and Percona XtraBackup with the Galera library to enable synchronous multi-source replication.

A *cluster* consists of *nodes*, where each node contains the same set of data synchronized accross nodes. The recommended configuration is to have at least 3 nodes, but you can have 2 nodes as well. Each node is a regular MySQL Server instance (for example, Percona Server). You can convert an existing MySQL Server instance to a node and run the cluster using this node as a base. You can also detach any node from the cluster and use it as a regular MySQL Server instance.

Benefits

- When you execute a query, it is executed locally on the node. All data is available locally, no need for remote access.
- No central management. You can loose any node at any point of time, and the cluster will continue to function without any data loss.
- Good solution for scaling a read workload. You can put read queries to any of the nodes.

Drawbacks

- Overhead of provisioning new node. When you add a new node, it has to copy the full data set from one of existing nodes. If it is 100 GB, it copies 100 GB.
- This can't be used as an effective write scaling solution. There might be some improvements in write throughput when you run write traffic to 2 nodes versus all traffic to 1 node, but you can't expect a lot. All writes still have to go on all nodes.
- You have several duplicates of data: for 3 nodes you have 3 duplicates.

3.1.1 Components

Percona XtraDB Cluster https://www.percona.com/software/mysql-database/percona-xtradb-cluster is based on Percona Server for MySQL running with the XtraDB storage engine. It uses the Galera library, which is an implementation of the write set replication (wsrep) API developed by Codership Oy. The default and recommended data transfer method is via Percona XtraBackup.

Last update: 2022-08-16

3.2 Percona XtraDB Cluster limitations

The following limitations apply to Percona XtraDB Cluster:

• Replication works only with InnoDB storage engine.

Any writes to tables of other types are not replicated.

• Unsupported queries:

LOCK TABLES and UNLOCK TABLES is not supported in multi-source setups

Lock functions, such as GET_LOCK(), RELEASE_LOCK(), and so on

• Query log cannot be directed to table.

If you enable query logging, you must forward the log to a file:

log output = FILE

Use general_log and general_log_file to choose query logging and the log file name.

• Maximum allowed transaction size is defined by the wsrep_max_ws_rows and wsrep_max_ws_size variables.

LOAD DATA INFILE processing will commit every 10 000 rows. So large transactions due to LOAD DATA will be split to series of small transactions.

• Transaction issuing COMMIT may still be aborted at that stage.

Due to cluster-level optimistic concurrency control, there can be two transactions writing to the same rows and committing in separate Percona XtraDB Cluster nodes, and only one of the them can successfully commit. The failing one will be aborted. For cluster-level aborts, Percona XtraDB Cluster gives back deadlock error code:

Error message 🗡

(Error: 1213 SQLSTATE: 40001 (ER_LOCK_DEADLOCK)).

• XA transactions are not supported

Due to possible rollback on commit.

• Write throughput of the whole cluster is limited by the weakest node.

If one node becomes slow, the whole cluster slows down. If you have requirements for stable high performance, then it should be supported by corresponding hardware.

• Minimal recommended size of cluster is 3 nodes.

The 3rd node can be an arbitrator.

• enforce_storage_engine=InnoDB is not compatible with wsrep_replicate_myisam=OFF

wsrep_replicate_myisam is set to OFF by default.

• Avoid ALTER TABLE ... IMPORT/EXPORT workloads when running Percona XtraDB Cluster in cluster mode.

It can lead to node inconsistency if not executed in sync on all nodes.

• All tables must have a primary key.

This ensures that the same rows appear in the same order on different nodes. The DELETE statement is not supported on tables without a primary key.

🖍 🖍 See also

Galera Documentation: Tables without Primary Keys

· Avoid reusing the names of persistent tables for temporary tables

Although MySQL does allow having temporary tables named the same as persistent tables, this approach is not recommended.

Galera Cluster blocks the replication of those persistent tables the names of which match the names of temporary tables.

With wsrep_debug set to 1, the error log may contain the following message:

Error message ~ ... [Note] WSREP: TO BEGIN: -1, 0 : create table t (i int) engine=innodb

```
... [Note] WSREP: TO isolation skipped for: 1, sql: create table t (i int) engine=innodb.Only temporary tables affected.
```

🖍 See also

MySQL Documentation: Problems with temporary tables

As of version 8.0.21, an INPLACE ALTER TABLE query takes an internal shared lock on the table during the execution of the query. The LOCK=NONE clause is no longer allowed for all of the INPLACE ALTER TABLE queries due to this change.

This change addresses a deadlock, which could cause a cluster node to hang in the following scenario:

- An INPLACE ALTER TABLE query in one session or being applied as Total Order Isolation (TOI)
- A DML on the same table from another session

Do not use one or more dot characters (.) when defining the values for the following variables:

- log_bin
- log_bin_index

MySQL and **XtraBackup** handles the value in different ways and this difference causes unpredictable behavior.

Last update: 2023-01-20

3.3 Understand version numbers

A version number identifies the product release. The product contains the latest Generally Available (GA) features at the time of that release.

8.0.20	-11.	2
Base version	Minor build	Custom build

Percona uses semantic version numbering, which follows the pattern of base version, minor build, and an optional custom build. Percona assigns unique, non-negative integers in increasing order for each minor build release. The version number combines the base Percona Server for MySQL version number, the minor build version, and the custom build version, if needed.

The version numbers for Percona XtraDB Cluster 8.0.20-11.2 define the following information:

- Base version the leftmost set of numbers that indicate the Percona Server for MySQL version used as a base. An increase in the base version resets the minor build version and the custom build version to 0.
- Minor build version an internal number that increases with every Percona XtraDB Cluster release, and the custom build number is reset to 0.
- Custom build version an optional number assigned to custom builds used for bug fixes. The features don't change unless the fixes include those features. For example, Percona XtraDB Cluster 8.0.20-11.1, 8.0.20-11.2, and 8.0.20-11.3 are based on the same Percona Server for MySQL version and minor build version but are custom build versions.

Last update: 2022-12-28

4. Features

4.1 High availability

In a basic setup with 3 nodes, Percona XtraDB Cluster will continue to function if you take any of the nodes down. At any point in time, you can shut down any node to perform maintenance or make configuration changes. Even in unplanned situations (like a node crashing or if it becomes unavailable over the network), the Percona XtraDB Cluster will continue to work and you'll be able to run queries on working nodes.

If there were changes to data while a node was down, there are two options that the node may use when it joins the cluster again:

• State Snapshot Transfer (SST) is when all data is copied from one node to another.

SST is usually used when a new node joins the cluster and receives all data from an existing node. Percona XtraDB Cluster uses **xtrabackup** for SST.

SST using xtrabackup does not require the READ LOCK command for the entire syncing process, only for syncing frm files (the same as with a regular backup).

• Incremental State Transfer (IST) is when only incremental changes are copied from one node to another.

Even without locking your cluster in read-only state, SST may be intrusive and disrupt normal operation of your services. IST lets you avoid that. If a node goes down for a short period of time, it can fetch only those changes that happened while it was down. IST is implemeted using a caching mechanism on nodes. Each node contains a cache, ring-buffer (the size is configurable) of last N changes, and the node is able to transfer part of this cache. Obviously, IST can be done only if the amount of changes needed to transfer is less than N. If it exceeds N, then the joining node has to perform SST.

You can monitor the current state of a node using the following command:

SHOW STATUS LIKE 'wsrep_local_state_comment';

When a node is in Synced (6) state, it is part of the cluster and ready to handle traffic.

Last update: 2023-07-21

4.2 Percona XtraDB Cluster strict mode

The Percona XtraDB Cluster (PXC) Strict Mode is designed to avoid the use of tech preview features and unsupported features in PXC. This mode performs a number of validations at startup and during runtime.

Depending on the actual mode you select, upon encountering a failed validation, the server will either throw an error (halting startup or denying the operation), or log a warning and continue running as normal. The following modes are available:

- DISABLED : Do not perform strict mode validations and run as normal.
- PERMISSIVE : If a validation fails, log a warning and continue running as normal.
- ENFORCING: If a validation fails during startup, halt the server and throw an error. If a validation fails during runtime, deny the operation and throw an error.
- MASTER: The same as ENFORCING except that the validation of explicit table locking is not performed. This mode can be used with clusters in which write operations are isolated to a single node.

By default, PXC Strict Mode is set to ENFORCING, except if the node is acting as a standalone server or the node is bootstrapping, then PXC Strict Mode defaults to DISABLED.

It is recommended to keep PXC Strict Mode set to ENFORCING, because in this case whenever Percona XtraDB Cluster encounters a tech preview feature or an unsupported operation, the server will deny it. This will force you to re-evaluate your Percona XtraDB Cluster configuration without risking the consistency of your data.

If you are planning to set PXC Strict Mode to anything else than ENFORCING, you should be aware of the limitations and effects that this may have on data integrity. For more information, see Validations.

To set the mode, use the pxc_strict_mode variable in the configuration file or the --pxc-strict-mode option during mysqld startup.

/ Note

It is better to start the server with the necessary mode (the default ENFORCING is highly recommended). However, you can dynamically change it during runtime. For example, to set PXC Strict Mode to PERMISSIVE, run the following command:

mysql> SET GLOBAL pxc_strict_mode=PERMISSIVE;

🧪 Note

To further ensure data consistency, it is important to have all nodes in the cluster running with the same configuration, including the value of pxc_strict_mode variable.

4.2.1 Validations

PXC Strict Mode validations are designed to ensure optimal operation for common cluster setups that do not require tech preview features and do not rely on operations not supported by Percona XtraDB Cluster.

🔒 Warning

If an unsupported operation is performed on a node with pxc_strict_mode set to DISABLED or PERMISSIVE, it will not be validated on nodes where it is replicated to, even if the destination node has pxc_strict_mode set to ENFORCING.

This section describes the purpose and consequences of each validation.

Group replication

Group replication is a feature of MySQL that provides distributed state machine replication with strong coordination between servers. It is implemented as a plugin which, if activated, may conflict with PXC. Group replication cannot be activated to run alongside PXC. However, you can migrate to PXC from the environment that uses group replication.

For the strict mode to work correctly, make sure that the group replication plugin is *not active*. In fact, if pxc_strict_mode is set to ENFORCING or MASTER, the server will stop with an error:

Error message with pxc_strict_mode set to ENFORCING or MASTER

The error message

Group replication cannot be used with PXC in strict mode.

If pxc_strict_mode is set to DISABLED you can use group replication at your own risk. Setting pxc_strict_mode to PERMISSIVE will result in a warning.

Warning message with pxc_strict_mode set to PERMISSIVE

📒 Warning message

Using group replication with PXC is only supported for migration. Please make sure that group replication is turned off once all data is migrated to PXC.

Storage engine

Percona XtraDB Cluster currently supports replication only for tables that use a transactional storage engine (XtraDB or InnoDB). To ensure data consistency, the following statements should not be allowed for tables that use a non-transactional storage engine (MyISAM, MEMORY, CSV, and others):

- Data manipulation statements that perform writing to table (for example, INSERT, UPDATE, DELETE, etc.)
- The following administrative statements: CHECK, OPTIMIZE, REPAIR, and ANALYZE
- TRUNCATE TABLE and ALTER TABLE

Depending on the selected mode, the following happens:

DISABLED

At startup, no validation is performed.

At runtime, all operations are permitted.

PERMISSIVE

At startup, no validation is performed.

At runtime, all operations are permitted, but a warning is logged when an undesirable operation is performed on an unsupported table.

ENFORCING or MASTER

At startup, no validation is performed.

At runtime, any undesirable operation performed on an unsupported table is denied and an error is logged.

/ Note

Unsupported tables can be converted to use a supported storage engine.

MyISAM replication

Percona XtraDB Cluster provides support for replication of tables that use the MyISAM storage engine. The use of the MyISAM storage engine in a cluster is not recommended and if you use the storage engine, this is

your own risk. Due to the non-transactional nature of MyISAM, the storage engine is not fully-supported in Percona XtraDB Cluster.

MyISAM replication is controlled using the wsrep_replicate_myisam variable, which is set to OFF by default. Due to its unreliability, MyISAM replication should not be enabled if you want to ensure data consistency.

Depending on the selected mode, the following happens:

DISABLED

At startup, no validation is performed.

At runtime, you can set wsrep_replicate_myisam to any value.

PERMISSIVE

At startup, if wsrep_replicate_myisam is set to 0N, a warning is logged and startup continues.

At runtime, it is permitted to change wsrep_replicate_myisam to any value, but if you set it to ON, a warning is logged.

ENFORCING or MASTER

At startup, if wsrep replicate myisam is set to ON, an error is logged and startup is aborted.

At runtime, any attempt to change wsrep_replicate_myisam to ON fails and an error is logged.

note 🖍

The wsrep_replicate_myisam variable controls *replication* for MyISAM tables, and this validation only checks whether it is allowed. Undesirable operations for MyISAM tables are restricted using the Storage engine validation.

Binary log format

Percona XtraDB Cluster supports only the default row-based binary logging format. In 8.0, setting the binlog_format variable to anything but ROW at startup or runtime is not allowed regardless of the value of the pxc_strict_mode variable.

Tables without primary keys

Percona XtraDB Cluster cannot properly propagate certain write operations to tables that do not have primary keys defined. Undesirable operations include data manipulation statements that perform writing to table (especially DELETE).

Depending on the selected mode, the following happens:

DISABLED

At startup, no validation is performed.

At runtime, all operations are permitted.

PERMISSIVE

At startup, no validation is performed.

At runtime, all operations are permitted, but a warning is logged when an undesirable operation is performed on a table without an explicit primary key defined.

ENFORCING or MASTER

At startup, no validation is performed.

At runtime, any undesirable operation performed on a table without an explicit primary key is denied and an error is logged.

Log output

Percona XtraDB Cluster does not support tables in the MySQL database as the destination for log output. By default, log entries are written to file. This validation checks the value of the log_output variable.

Depending on the selected mode, the following happens:

DISABLED

At startup, no validation is performed.

At runtime, you can set log_output to any value.

PERMISSIVE

At startup, if log_output is set only to TABLE, a warning is logged and startup continues.

At runtime, it is permitted to change log_output to any value, but if you set it only to TABLE, a warning is logged.

ENFORCING or MASTER

At startup, if log_output is set only to TABLE , an error is logged and startup is aborted.

At runtime, any attempt to change log_output only to TABLE fails and an error is logged.

Explicit table locking

Percona XtraDB Cluster provides only the tech-preview-level of support for explicit table locking operations, The following undesirable operations lead to explicit table locking and are covered by this validation:

- LOCK TABLES
- GET_LOCK() and RELEASE_LOCK()
- FLUSH TABLES <tables> WITH READ LOCK
- Setting the SERIALIZABLE transaction level

Depending on the selected mode, the following happens:

DISABLED or MASTER

At startup, no validation is performed.

At runtime, all operations are permitted.

PERMISSIVE

At startup, no validation is performed.

At runtime, all operations are permitted, but a warning is logged when an undesirable operation is performed.

ENFORCING

At startup, no validation is performed.

At runtime, any undesirable operation is denied and an error is logged.

Auto-increment lock mode

The lock mode for generating auto-increment values must be *interleaved* to ensure that each node generates a unique (but non-sequential) identifier.

This validation checks the value of the innodb_autoinc_lock_mode variable. By default, the variable is set to 1 (*consecutive* lock mode), but it should be set to 2 (*interleaved* lock mode).

Depending on the strict mode selected, the following happens:

DISABLED

At startup, no validation is performed.

PERMISSIVE

At startup, if innodb_autoinc_lock_mode is not set to 2, a warning is logged and startup continues.

ENFORCING or MASTER

At startup, if innodb_autoinc_lock_mode is not set to 2, an error is logged and startup is aborted.

This validation is not performed during runtime, because the <code>innodb_autoinc_lock_mode</code> variable cannot be set dynamically.

Combine schema and data changes in a single statement

With strict mode set to ENFORCING, Percona XtraDB Cluster does not support statements, because they combine both schema and data changes. Note that tables in the SELECT clause should be present on all replication nodes.

With strict mode set to PERMISSIVE or DISABLED, CREATE TABLE ... AS SELECT (CTAS) statements are replicated using the method to ensure consistency.

In Percona XtraDB Cluster 5.7, CREATE TABLE ... AS SELECT (CTAS) statements were replicated using DML writesets when strict mode was set to PERMISSIVE or DISABLED.

Important

MyISAM tables are created and loaded even if wsrep_replicate_myisam equals to 1. Percona XtraDB Cluster does not recommend using the MyISAM storage engine. The support for MyISAM may be removed in a future release.

🖍 See also

MySQL Bug System: XID inconsistency on master-slave with CTAS https://bugs.mysql.com/bug.php?id=93948

Mode	Behavior
DISABLED	At startup, no validation is performed. At runtime, all operations are permitted.
PERMISSIVE	At startup, no validation is performed. At runtime, all operations are permitted, but a warning is logged when a CREATE TABLE AS SELECT (CTAS) operation is performed.

Depending on the strict mode selected, the following happens:

Mode	Behavior
ENFORCING	At startup, no validation is performed. At runtime, any CTAS operation is denied and an error is logged.

🗴 Important

Although CREATE TABLE ... AS SELECT (CTAS) operations for temporary tables are permitted even in STRICT mode, temporary tables should not be used as *source* tables in CREATE TABLE ... AS SELECT (CTAS) operations due to the fact that temporary tables are not present on all nodes.

If node-1 has a temporary and a non-temporary table with the same name, CREATE TABLE ... AS SELECT (CTAS) on node-1 will use temporary and CREATE TABLE ... AS SELECT (CTAS) on node-2 will use the non-temporary table resulting in a data level inconsistency.

Discard and import tablespaces

DISCARD TABLESPACE and IMPORT TABLESPACE are not replicated using TOI. This can lead to data inconsistency if executed on only one node.

Depending on the strict mode selected, the following happens:

DISABLED

At startup, no validation is performed.

At runtime, all operations are permitted.

PERMISSIVE

At startup, no validation is performed.

At runtime, all operations are permitted, but a warning is logged when you discard or import a tablespace.

ENFORCING

At startup, no validation is performed.

At runtime, discarding or importing a tablespace is denied and an error is logged.

Major version check

This validation checks that the protocol version is the same as the server major version. This validation protects the cluster against writes attempted on already upgraded nodes.

Expected output

```
ERROR 1105 (HY000): Percona-XtraDB-Cluster prohibits use of multiple major versions while accepting write workload with pxc_strict_mode = ENFORCING or MASTER
```

4.3 Online schema upgrade

Database schemas must change as applications change. For a cluster, the schema upgrade must occur while the system is online. A synchronous cluster requires all active nodes have the same data. Schema updates are performed using Data Definition Language (DDL) statements, such as ALTER TABLE <table_name> DROP COLUMN <column_name>.

The DDL statements are non-transactional, so these statements use up-front locking to avoid the chance of deadlocks and cannot be rolled back. We recommend that you test your schema changes, especially if you must run an ALTER statement on large tables. Verify the backups before updating the schemas in the production environment. A failure in a schema change can cause your cluster to drop nodes and lose data.

Method Name	Reason for use	Description
TOI or Total Order Isolation	Consistency is important. Other transactions are blocked while the cluster processes the DDL statements.	This is the default method for the wsrep-OSU-method variable. The isolation of the DDL statement guarantees consistency. The DDL replication uses a Statement format. Each node processes the replicated DDL statement at same position in the replication stream. All other writes must wait until the DDL statement is executed. While a DDL statement is running, any long-running transactions in progress and using the same resource receive a deadlock error at commit and are rolled back. The pt-online-schema-change in the <i>Percona</i> Toolkit can alter the table without using locks. There are limitations: only InnoDB tables can be altered, and the wsrep_OSU_method must be TOI.
RSU or Rolling Schema Upgrade	This method guarantees high availability during the schema upgrades.	The node desynchronizes with the cluster and disables flow control during the execution of the DDL statement. The rest of the cluster is not affected. After the statement execution, the node applies delayed events and synchronizes with the cluster. Although the cluster is active, during the process some nodes have the newer schema and some nodes have the older schema. The RSU method is a manual operation. For this method, the gcache must be large enough to store the data for the duration of the DDL change.
NBO or Non- Blocking Operation	This method is used when consistency is important and uses a more efficient locking strategy.	This method is similar to TOI. DDL operations acquire an exclusive metadata lock on the table or schema at a late stage of the operation when updating the table or schema definition. Attempting a State Snapshot Transfer (SST) fails during the NBO operation. This mode uses a more efficient locking strategy and avoids the TOI issue of long-running DDL statements blocking other updates in the cluster.

Percona XtraDB Cluster supports the following methods for making online schema changes:

Last update: 2023-07-21

4.4 Non-Blocking Operations (NBO) method for Online Scheme Upgrades (OSU)

An Online Schema Upgrade can be a daily issue in an environment with accelerated development and deployment. The task becomes more difficult as the data grows. An ALTER TABLE statement is a multi-step operation and must run until it is complete. Aborting the statement may be more expensive than letting it complete.

The Non-Blocking Operations (NBO) method is similar to the TOI method (see Online Schema Upgrade for more information on the available types of online schema upgrades). Every replica processes the DDL statement at the same point in the cluster transaction stream, and other transactions cannot commit during the operation. The NBO method provides a more efficient locking strategy and avoids the TOI issue of long-running DDL statements blocking cluster updates.

In the NBO method, the supported DDL statement acquires a metadata lock on the table or schema at a late stage of the operation. The lock_wait_timeout system variable defines the timeout, measured in seconds, to acquire metadata locks. The default value, 3153600, could cause infinite waits and should not be used with the NBO method.

Attempting a State Snapshot Transfer (SST) fails during the NBO operation.

To dynamically set the NBO mode in the client, run the following statement:

SET SESSION wsrep_OSU_method='NBO';

4.4.1 Supported DDL statements

The NBO method supports the following DDL statements:

- ALTER TABLE
- ALTER INDEX
- CREATE INDEX
- DROP INDEX

4.4.2 Limitations

The NBO method does not support the following:

- Running two DDL statements with conflicting locks on the same table. For example, you cannot run two ALTER TABLE statements for an employees table.
- Modifying a table changed during the NBO operation. However, you can modify other tables and execute NBO queries on other tables.

See the Percona XtraDB Cluster 8.0.25-15.1 Release notes for the latest information.

5. Quickstart guide

5.1 Quickstart Guide for Percona XtraDB Cluster

Percona XtraDB Cluster (PXC) is a 100% open source, enterprise-grade, highly available clustering solution for MySQL multi-master setups based on Galera. PXC helps enterprises minimize unexpected downtime and data loss, reduce costs, and improve performance and scalability of your database environments supporting your critical business applications in the most demanding public, private, and hybrid cloud environments.

5.1.1 Install Percona XtraDB Cluster

You can install Percona XtraDB Cluster using different methods.

- Use the Percona Repositories
- Use APT
- Use YUM
- Use binary tarballs
- Use Docker

5.1.2 For superior and optimized performance

Percona Server for MySQL (PS) is a freely available, fully compatible, enhanced, and open source drop-in replacement for any MySQL database. It provides superior and optimized performance, greater scalability and availability, enhanced backups, increased visibility, and instrumentation. Percona Server for MySQL is trusted by thousands of enterprises to provide better performance and concurrency for their most demanding workloads.

Install Percona Server for MySQL.

5.1.3 For backups and restores

Percona XtraBackup (PXB) is a 100% open source backup solution for all versions of Percona Server for MySQL and MySQL® that performs online non-blocking, tightly compressed, highly secure full backups on transactional systems. Maintain fully available applications during planned maintenance windows with Percona XtraBackup.

Install Percona XtraBackup

5.1.4 For Monitoring and Management

Percona Monitoring and Management (PMM)monitors and provides actionable performance data for MySQL variants, including Percona Server for MySQL, Percona XtraDB Cluster, Oracle MySQL Community Edition, Oracle MySQL Enterprise Edition, and MariaDB. PMM captures metrics and data for the InnoDB, XtraDB, and MyRocks storage engines, and has specialized dashboards for specific engine details.

Install PMM and connect your MySQL instances to it.

5.2 Get started with Percona XtraDB Cluster

This guide describes the procedure for setting up Percona XtraDB Cluster.

Examples provided in this guide assume there are three Percona XtraDB Cluster nodes, as a common choice for trying out and testing:

Node	Host	IP
Node 1	рхсі	192.168.70.61
Node 2	pxc2	192.168.70.62
Node 3	рхс3	192.168.70.63

🖍 Note

Avoid creating a cluster with two or any even number of nodes, because this can lead to split brain.

The following procedure provides an overview with links to details for every step:

• Install Percona XtraDB Cluster on all nodes and set up root access for them.

It is recommended to install from official Percona repositories:

- On Red Hat and CentOS, install using YUM.
- On Debian and Ubuntu, install using APT.
- Configure all nodes with relevant settings required for write-set replication.

This includes path to the Galera library, location of other nodes, etc.

• Bootstrap the first node to initialize the cluster.

This must be the node with your main database, which will be used as the data source for the cluster.

• Add other nodes to the cluster.

Data on new nodes joining the cluster is overwritten in order to synchronize it with the cluster.

• Verify replication.

Although cluster initialization and node provisioning is performed automatically, it is a good idea to ensure that changes on one node actually replicate to other nodes.

• Install ProxySQL.

To complete the deployment of the cluster, a high-availability proxy is required. We recommend installing ProxySQL on client nodes for efficient workload management across the cluster without any changes to the applications that generate queries.

5.2.1 Percona Monitoring and Management

Percona Monitoring and Management is the best choice for managing and monitoring Percona XtraDB Cluster performance. It provides visibility for the cluster and enables efficient troubleshooting.

6. Get started

6.1 Install Percona XtraDB Cluster

Install Percona XtraDB Cluster on all hosts that you are planning to use as cluster nodes and ensure that you have root access to the MySQL server on each one.

We gather Telemetry data in the Percona packages and Docker images.

It is recommended to install Percona XtraDB Cluster from official Percona software repositories using the corresponding package manager for your system:

- Debian or Ubuntu
- Red Hat or CentOS

Important

After installing Percona XtraDB Cluster the mysql service is *stopped* but *enabled* so that it may start the next time the system is restarted. The service starts if the the grastate.dat file exists and the value of seqno is not **-1**.

See also

More information about Galera state information in Index of files created by PXC grastat.dat

6.1.1 Installation alternatives

Percona also provides a generic tarball with all required files and binaries for manual installation:

Installing Percona XtraDB Cluster from Binary Tarball

If you want to build Percona XtraDB Cluster from source, see Compiling and Installing from Source Code.

If you want to run Percona XtraDB Cluster using Docker, see Running Percona XtraDB Cluster in a Docker Container.

6.1.2 Product version numbering

The version number in PXC releases contains the following components:

- The version of Percona Server for MySQL that the given PXC release is based on
- The sequence number which represents the PXC built.

For example, version number 8.0.18–9.3 means that this is the third PXC build based on Percona Server for MySQL 8.0.18–9.

6.2 Install Percona XtraDB Cluster on Debian or Ubuntu

Specific information on the supported platforms, products, and versions is described in Percona Software and Platform Lifecycle.

The packages are available in the official Percona software repository and on the download page. It is recommended to install Percona XtraDB Cluster from the official repository using APT.

We gather Telemetry data in the Percona packages and Docker images.

6.2.1 Prerequisites

- You need to have root access on the node where you will be installing Percona XtraDB Cluster (either logged in as a user with root privileges or be able to run commands with sudo).
- Make sure that the following ports are not blocked by firewall or used by other software. Percona XtraDB Cluster requires them for communication.
- 3306
- 4444
- 4567
- 4568

🖍 See also

For more information, see Enabling AppArmor.

6.2.2 Install from Repository

1. Update the sytem:

sudo apt update

2. Install the necessary packages:

sudo apt install -y wget gnupg2 lsb-release curl

3. Download the repository package

wget https://repo.percona.com/apt/percona-release_latest.generic_all.deb

4. Install the package with dpkg:

sudo dpkg -i percona-release_latest.generic_all.deb

5. Refresh the local cache to update the package information:

sudo apt update

6. Enable the release repository for *Percona XtraDB Cluster*.

sudo percona-release setup pxc80

7. Install the cluster:

sudo apt install -y percona-xtradb-cluster

During the installation, you are requested to provide a password for the root user on the database node.

If needed, you could also install the percona-xtradb-cluster-full meta-package, which includes the following additional packages:

- libperconaserverclient21
- libperconaserverclient21-dev
- percona-xtradb-cluster
- percona-xtradb-cluster-client
- percona-xtradb-cluster-common
- percona-xtradb-cluster-dbg
- percona-xtradb-cluster-full
- percona-xtradb-cluster-garbd
- percona-xtradb-cluster-garbd-debug
- percona-xtradb-cluster-server
- percona-xtradb-cluster-server-debug
- percona-xtradb-cluster-source
- percona-xtradb-cluster-test

6.2.3 Next steps

After you install Percona XtraDB Cluster and stop the mysql service, configure the node according to the procedure described in Configuring Nodes for Write-Set Replication.

Last update: 2023-11-01

6.3 Install Percona XtraDB Cluster on Red Hat Enterprise Linux and CentOS

A list of the supported platforms by products and versions is available in Percona Software and Platform Lifecycle.

We gather Telemetry data in the Percona packages and Docker images.

You can install Percona XtraDB Cluster with the following methods:

- Use the official repository using YUM
- Download and manually install the Percona XtraDB Cluster packages from Percona Product Downloads.
- Use the Percona Software repositories

This documentation describes using the Percona Software repositories.

6.3.1 Prerequisites

Installing Percona XtraDB Cluster requires that you either are logged in as a user with root privileges or can run commands with sudo.

Percona XtraDB Cluster requires the specific ports for communication. Make sure that the following ports are available:

- 3306
- 4444
- 4567
- 4568

For information on SELinux, see Enabling SELinux.

6.3.2 Install from Percona Software Repository

For more information on the Percona Software repositories and configuring Percona Repositories with percona-release, see the Percona Software Repositories Documentation.

Install on Red Hat 7 Install on Red Hat 8 or later
\$ sudo yum install https://repo.percona.com/yum/percona-release-latest.noarch.rpm
\$ sudo percona-release enable tools release
\$ sudo yum install percona-xtradb-cluster
\$ sudo yum install https://repo.percona.com/yum/percona-release-latest.noarch.rpm
\$ sudo percona-release setup pxc-80
\$ sudo yum install percona-xtradb-cluster

6.3.3 After installation

After the installation, start the mysql service and find the temporary password using the grep command.

```
$ sudo service mysql start
$ sudo grep 'temporary password' /var/log/mysqld.log
```

Use the temporary password to log into the server:

\$ mysql -u root -p

Run an ALTER USER statement to change the temporary password, exit the client, and stop the service.

```
mysql> ALTER USER 'root'@'localhost' IDENTIFIED BY 'rootPass';
mysql> exit
$ sudo service mysql stop
```

6.3.4 Next steps

Configure the node according to the procedure described in Configuring Nodes for Write-Set Replication.

```
Last update: 2023-11-01
```

6.4 Install Percona XtraDB Cluster from Binary Tarball

Percona provides generic tarballs with all required files and binaries for manual installation.

You can download the appropriate tarball package from https://www.percona.com/downloads/Percona-XtraDB-Cluster-80

Version updates

Starting with *Percona XtraDB Cluster* 8.0.20-11, the **Linux - Generic** section lists only full or minimal tar files. Each tarball file replaces the multiple tar file listing used in earlier versions and supports all distributions.

Important

Starting with Percona XtraDB Cluster 8.0.21, Percona does not provide a tarball for RHEL 6/CentOS 6 (glibc2.12).

The version number in the tarball name must be substituted with the appropriate version number for your system. To indicate that such a substitution is needed in statements, we use <version-number>.

Name	Туре	Description
Percona-XtraDB-Cluster Linux.x86_64.glibc2.17.tar.gz	Full	Contains binary files, libraries, test files, and debug symbols
Percona-XtraDB-Cluster Linux.x86_64.glibc2.17.minimal.tar.gz	Minimal	Contains binary files and libraries but does not include test files, or debug symbols

For installations before *Percona XtraDB Cluster* 8.0.20-11, the **Linux - Generic** section contains multiple tarballs based on the operating system names:

Percona-XtraDB-Cluster_8.0.18-9.3_Linux.x86_64.bionic.tar.gz
Percona-XtraDB-Cluster_8.0.18-9.3_Linux.x86_64.buster.tar.gz

For example, you can use curl as follows:

```
$ curl -0 https://downloads.percona.com/downloads/Percona-XtraDB-Cluster-LATEST/Percona-
XtraDB-Cluster-8.0.27/binary/tarball/Percona-XtraDB-
Cluster 8.0.27-18.1 Linux.x86 64.glibc2.17-minimal.tar.gz
```

Check your system to make sure the packages that the PXC version requires are installed.

For Debian or Ubuntu:

```
$ sudo apt-get install -y \
socat libdbd-mysql-perl \
libaiol libc6 libcurl3 libev4 libgcc1 libgcrypt20 \
libgpg-error0 libssl1.1 libstdc++6 zliblg libatomic1
```

For Red Hat Enterprise Linux or CentOS:

```
$ sudo yum install -y openssl socat \
procps-ng chkconfig procps-ng coreutils shadow-utils \
```

Last update: 2023-07-21

6.5 Compile and install from Source Code

If you want to compile Percona XtraDB Cluster, you can find the source code on GitHub. Before you begin, make sure that the following packages are installed:

	apt	yum
Git	git	git
SCons	scons	scons
GCC	gcc	gcc
g++	g++	gcc-c++
OpenSSL	openssl	openssl
Check	check	check
CMake	cmake	cmake
Bison	bison	bison
Boost	libboost-all-dev	boost-devel
Asio	libasio-dev	asio-devel
Async I/O	libaio-dev	libaio-devel
ncurses	libncurses5-dev	ncurses-devel
Readline	libreadline-dev	readline-devel
РАМ	libpam-dev	pam-devel
socat	socat	socat
curl	libcurl-dev	libcurl-devel

You will likely have all or most of the packages already installed. If you are not sure, run one of the following commands to install any missing dependencies:

• For Debian or Ubuntu:

```
$ sudo apt install -y git scons gcc g++ openssl check cmake bison \
libboost-all-dev libasio-dev libaio-dev libncurses5-dev libreadline-dev \
libpam-dev socat libcurl-dev
```

• For Red Hat Enterprise Linux or CentOS:

```
$ sudo yum install -y git scons gcc gcc-c++ openssl check cmake bison \
boost-devel asio-devel libaio-devel ncurses-devel readline-devel pam-devel \
socat libcurl-devel
```

To compile Percona XtraDB Cluster from source code:

1. Clone the Percona XtraDB Cluster repository:

\$ git clone https://github.com/percona/percona-xtradb-cluster.git

Important

Clone the latest repository or update it to the latest state. Old codebase may not be compatible with the build script.

2. Check out the 8.0 branch and initialize submodules:

```
$ cd percona-xtradb-cluster
$ git checkout 8.0
$ git submodule update --init --recursive
```

3. Download the matching Percona XtraBackup 8.0 tarball (*.tar.gz) for your operating system from Percona Downloads.

The following example extract the Percona XtraBackup 8.0.32-25 tar.gz file to the target directory ./pxc-build:

```
```{.bash data-prompt="$"}
$ tar -xvf percona-xtrabackup-8.0.32-25-Linux-x86_64.glibc2.17.tar.gz -C ./pxc-build
```
```

1. Run the build script ./build-ps/build-binary.sh. By default, it attempts building into the current directory. Specify the target output directory, such as ./pxc-build:

```
$ mkdir ./pxc-build
$ ./build-ps/build-binary.sh ./pxc-build
```

When the compilation completes, pxc-build contains a tarball, such as Percona-XtraDB-Cluster-8.0.x86_64.tar.gz, that you can deploy on your system.

🖍 Note

The exact version and release numbers may differ.

Last update: 2023-07-21

6.6 Running Percona XtraDB Cluster in a Docker Container

Docker images of Percona XtraDB Cluster are hosted publicly on Docker Hub at https://hub.docker.com/r/percona/percona-xtradb-cluster/.

For more information about using Docker, see the Docker Docs. Make sure that you are using the latest version of Docker. The ones provided via apt and yum may be outdated and cause errors.

We gather Telemetry data in the Percona packages and Docker images.

Note

By default, Docker pulls the image from Docker Hub if the image is not available locally.

The image contains only the most essential binaries for Percona XtraDB Cluster to run. Some utilities included in a Percona Server for MySQL or MySQL installation might be missing from the Percona XtraDB Cluster Docker image.

The following procedure describes how to set up a simple 3-node cluster for evaluation and testing purposes. Do not use these instructions in a production environment because the MySQL certificates generated in this procedure are self-signed. For a production environment, you should generate and store the certificates to be used by Docker.

In this procedure, all of the nodes run Percona XtraDB Cluster 8.0 in separate containers on one host:

1. Create a ~/pxc-docker-test/config directory.

2. Create a custom.cnf file with the following contents, and place the file in the new directory:

```
[mysqld]
ssl-ca = /cert/ca.pem
ssl-cert = /cert/server-cert.pem
ssl-key = /cert/server-key.pem
[client]
ssl-ca = /cert/ca.pem
ssl-cert = /cert/client-cert.pem
ssl-key = /cert/client-key.pem
[sst]
encrypt = 4
ssl-ca = /cert/ca.pem
ssl-cert = /cert/server-cert.pem
ssl-key = /cert/server-key.pem
```

3. Create a cert directory and generate self-signed SSL certificates on the host node:

```
$ mkdir -m 777 -p ~/pxc-docker-test/cert
docker run --name pxc-cert --rm -v ~/pxc-docker-test/cert:/cert
percona/percona-xtradb-cluster:8.0 mysql_ssl_rsa_setup -d /cert
```

4. Create a Docker network:

docker network create pxc-network

5. Bootstrap the cluster (create the first node):

```
docker run -d \
  -e MYSQL_ROOT_PASSWORD=test1234# \
  -e CLUSTER_NAME=pxc-cluster1 \
  --name=pxc-node1 \
  --net=pxc-network \
  -v ~/pxc-docker-test/cert:/cert \
  -v ~/pxc-docker-test/config:/etc/percona-xtradb-cluster.conf.d \
  percona/percona-xtradb-cluster:8.0
```

6. Join the second node:

```
docker run -d \
  -e MYSQL_ROOT_PASSWORD=test1234# \
  -e CLUSTER_NAME=pxc-cluster1 \
  -e CLUSTER_JOIN=pxc-node1 \
  --name=pxc-node2 \
  --net=pxc-network \
  -v ~/pxc-docker-test/cert:/cert \
  -v ~/pxc-docker-test/config:/etc/percona-xtradb-cluster.conf.d \
  percona/percona-xtradb-cluster:8.0
```

7. Join the third node:

```
docker run -d \
  -e MYSQL_ROOT_PASSWORD=test1234# \
  -e CLUSTER_NAME=pxc-cluster1 \
  -e CLUSTER_JOIN=pxc-node1 \
  --name=pxc-node3 \
  --net=pxc-network \
  -v ~/pxc-docker-test/cert:/cert \
  -v ~/pxc-docker-test/config:/etc/percona-xtradb-cluster.conf.d \
  percona/percona-xtradb-cluster:8.0
```

To verify the cluster is available, do the following:

1. Access the MySQL client. For example, on the first node:

```
$ sudo docker exec -it pxc-node1 /usr/bin/mysql -uroot -ptest1234#
```

Expected output 🗡

```
mysql: [Warning] Using a password on the command line interface can be insecure.
Welcome to the MySQL monitor. Commands end with ; or \g.
Your MySQL connection id is 12
....
You are enforcing ssl connection via unix socket. Please consider
switching ssl off as it does not make connection via unix socket
any more secure
mysgl>
```

2. View the wsrep status variables:

mysql> show status like 'wsrep%';

| Expected output Y | |
|--|---|
| | ++ |
| Variable_name | Value |
| wsrep_local_state_uuid | 625318e2-9e1c-11e7-9d07-aee70d98d8ac |
| wsrep_local_state_comment | Synced |
|
wsrep_incoming_addresses | 172.18.0.2:3306,172.18.0.3:3306,172.18.0.4:3306 |
|

|
 wsrep_ready | ON |
| 59 rows in set (0.02 sec) | |

Last update: 2023-11-01

6.7 Configure nodes for write-set replication

After installing Percona XtraDB Cluster on each node, you need to configure the cluster. In this section, we will demonstrate how to configure a three node cluster:

| Node | Host | IP |
|--------|------|---------------|
| Node 1 | рхс1 | 192.168.70.61 |
| Node 2 | рхс2 | 192.168.70.62 |
| Node 3 | рхс3 | 192.168.70.63 |

1. Stop the Percona XtraDB Cluster server. After the installation completes the server is not started. You need this step if you have started the server manually.

\$ sudo service mysql stop

2. Edit the configuration file of the first node to provide the cluster settings.

If you use Debian or Ubuntu, edit /etc/mysql/mysql.conf.d/mysqld.cnf:

```
wsrep_provider=/usr/lib/galera4/libgalera_smm.so
wsrep_cluster_name=pxc-cluster
wsrep_cluster_address=gcomm://192.168.70.61,192.168.70.62,192.168.70.63
```

If you use Red Hat or CentOS, edit /etc/my.cnf. Note that on these systems you set the wsrep_provider option to a different value:

```
wsrep_provider=/usr/lib64/galera4/libgalera_smm.so
wsrep_cluster_name=pxc-cluster
wsrep_cluster_address=gcomm://192.168.70.61,192.168.70.62,192.168.70.63
```

3. Configure node 1.

```
wsrep_node_name=pxc1
wsrep_node_address=192.168.70.61
pxc strict mode=ENFORCING
```

4. Set up *node* 2 and *node* 3 in the same way: Stop the server and update the configuration file applicable to your system. All settings are the same except for wsrep_node_name and wsrep_node_address.

For node 2

```
wsrep_node_name=pxc2
wsrep_node_address=192.168.70.62
```

For node 3

```
wsrep_node_name=pxc3
wsrep_node_address=192.168.70.63
```

5. Set up the traffic encryption settings. Each node of the cluster must use the same SSL certificates.

```
[mysqld]
wsrep_provider_options="socket.ssl_key=server-key.pem;socket.ssl_cert=server-
cert.pem;socket.ssl_ca=ca.pem"
```

```
[sst]
encrypt=4
ssl-key=server-key.pem
ssl-ca=ca.pem
ssl-cert=server-cert.pem
```

Important

In Percona XtraDB Cluster 8.0, the Encrypting Replication Traffic is enabled by default (via the pxc-encrypt-cluster-traffic variable).

The replication traffic encryption cannot be enabled on a running cluster. If it was disabled before the cluster was bootstrapped, the cluster must to stopped. Then set up the encryption, and bootstrap (see Bootstrapping the First Node) again.

See also

More information about the security settings in Percona XtraDB Cluster * Security Basics * Encrypting PXC Traffic * SSL Automatic Configuration

6.7.1 Template of the configuration file

Here is an example of a full configuration file installed on CentOS to /etc/my.cnf.

```
# Template my.cnf for PXC
# Edit to your requirements.
[client]
socket=/var/lib/mysql/mysql.sock
[mysqld]
```

server-id=1 datadir=/var/lib/mysql socket=/var/lib/mysql/mysql.sock log-error=/var/log/mysqld.log pid-file=/var/run/mysqld/mysqld.pid # Binary log expiration period is 604800 seconds, which equals 7 days binlog expire logs seconds=604800 # Path to Galera library wsrep_provider=/usr/lib64/galera4/libgalera_smm.so # Cluster connection URL contains IPs of nodes #If no IP is found, this implies that a new cluster needs to be created, #in order to do that you need to bootstrap this node wsrep cluster address=gcomm:// # In order for Galera to work correctly binlog format should be ROW binlog format=ROW # Slave thread to use wsrep slave threads=8 wsrep_log_conflicts # This changes how InnoDB autoincrement locks are managed and is a requirement for Galera innodb autoinc lock mode=2 # Node IP address #wsrep node address=192.168.70.63 # Cluster name wsrep cluster name=pxc-cluster #If wsrep node name is not specified, then system hostname will be used wsrep node name=pxc-cluster-node-1 #pxc strict mode allowed values: DISABLED,PERMISSIVE,ENFORCING,MASTER pxc strict mode=ENFORCING # SST method wsrep_sst_method=xtrabackup-v2

6.7.2 Next Steps: Bootstrap the first node

After you configure all your nodes, initialize Percona XtraDB Cluster by bootstrapping the first node according to the procedure described in Bootstrapping the First Node.

6.7.3 Essential configuration variables

wsrep_provider

Specify the path to the Galera library. The location depends on the distribution:

- Debian and Ubuntu: /usr/lib/galera4/libgalera_smm.so
- Red Hat and CentOS: /usr/lib64/galera4/libgalera_smm.so

wsrep_cluster_name

Specify the logical name for your cluster. It must be the same for all nodes in your cluster.

wsrep_cluster_address

Specify the IP addresses of nodes in your cluster. At least one is required for a node to join the cluster, but it is recommended to list addresses of all nodes. This way if the first node in the list is not available, the joining node can use other addresses.

Note

No addresses are required for the initial node in the cluster. However, it is recommended to specify them and properly bootstrap the first node. This will ensure that the node is able to rejoin the cluster if it goes down in the future.

wsrep_node_name

Specify the logical name for each individual node. If this variable is not specified, the host name will be used.

wsrep_node_address

Specify the IP address of this particular node.

wsrep_sst_method

By default, Percona XtraDB Cluster uses Percona XtraBackup for State Snapshot Transfer. xtrabackup-v2 is the only supported option for this variable. This method requires a user for SST to be set up on the initial node.

pxc_strict_mode

PXC Strict Mode is enabled by default and set to ENFORCING, which blocks the use of tech preview features and unsupported features in Percona XtraDB Cluster.

binlog_format

Galera supports only row-level replication, so set binlog_format=ROW.

default_storage_engine

Galera fully supports only the InnoDB storage engine. It will not work correctly with MyISAM or any other non-transactional storage engines. Set this variable to default_storage_engine=InnoDB.

innodb_autoinc_lock_mode

Galera supports only interleaved (2) lock mode for InnoDB. Setting the traditional (0) or consecutive (1) lock mode can cause replication to fail due to unresolved deadlocks. Set this variable to innodb autoinc_lock_mode=2.

Last update: 2023-10-19

6.8 Bootstrap the first node

After you configure all PXC nodes, initialize the cluster by bootstrapping the first node. The initial node must contain all the data that you want to be replicated to other nodes.

Bootstrapping implies starting the first node without any known cluster addresses: if the wsrep_cluster_address variable is empty, Percona XtraDB Cluster assumes that this is the first node and initializes the cluster.

Instead of changing the configuration, start the first node using the following command:

[root@pxc1 ~]# systemctl start mysql@bootstrap.service

When you start the node using the previous command, it runs in bootstrap mode with wsrep_cluster_address=gcomm://. This tells the node to initialize the cluster with wsrep_cluster_conf_id

variable set to 1. After you add other nodes to the cluster, you can then restart this node as normal, and it will use standard configuration again.

🧪 Note

A service started with <code>mysql@bootstrap</code> must be stopped using the same command. For example, the <code>systemctl</code> stop <code>mysql</code> command does not stop an instance started with the <code>mysql@bootstrap</code> command.

To make sure that the cluster has been initialized, run the following:

mysql@pxc1> show status like 'wsrep%';

The output shows that the cluster size is 1 node, it is the primary component, the node is in the Synced state, it is fully connected and ready for write-set replication.

| Expected output | |
|--|--|
| | + |
| Variable_name | Value |
| <pre>wsrep_local_state_uuid

wsrep_local_state
wsrep_local_state_comment

wsrep_cluster_size
wsrep_cluster_status
wsrep_connected

wsrep_ready</pre> | <pre>c2883338-834d-11e2-0800-03c9c68e41ec i 4 Synced 1 Primary 0N 0N</pre> |

6.8.1 Next steps

After initializing the cluster, you can add other nodes.

Last update: 2023-07-21

6.9 Add nodes to cluster

New nodes that are properly configured are provisioned automatically. When you start a node with the address of at least one other running node in the wsrep_cluster_address variable, this node automatically joins and synchronizes with the cluster.

Any existing data and configuration will be overwritten to match the data and configuration of the DONOR node. Do not join several nodes at the same time to avoid overhead due to large amounts of traffic when a new node joins. Percona XtraDB Cluster uses Percona XtraBackup for State Snapshot Transfer and the wsrep_sst_method variable is always set to xtrabackup-v2.

6.9.1 Start the second node

Start the second node using the following command:

[root@pxc2 ~]# systemctl start mysql

After the server starts, it receives SST automatically.

To check the status of the second node, run the following:

mysql@pxc2> show status like 'wsrep%';

| Expected output | |
|--|--|
| + | ++ |
| Variable_name | Value |
| <pre> wsrep_local_state_uuid wsrep_local_state wsrep_local_state wsrep_local_state_comment wsrep_cluster_size wsrep_cluster_status wsrep_connected wsrep_provider_capabilities wsrep_provider_name wsrep_provider_vendor wsrep_provider_version wsrep_ready </pre> | <pre>a08247c1-5807-11ea-b285-e3a50c8efb41 4 4 Synced 2 Primary 0N Find Content of the set o</pre> |
| 75 rows in set (0.00 sec) | |

The output of SHOW STATUS shows that the new node has been successfully added to the cluster. The cluster size is now 2 nodes, it is the primary component, and it is fully connected and ready to receive write-set replication.

If the state of the second node is Synced as in the previous example, then the node received full SST is synchronized with the cluster, and you can proceed to add the next node.

🖍 Note

If the state of the node is Joiner, it means that SST hasn't finished. Do not add new nodes until all others are in Synced state.

6.9.2 Starting the Third Node

To add the third node, start it as usual:

```
[root@pxc3 ~]# systemctl start mysql
```

To check the status of the third node, run the following:

mysql@pxc3> show status like 'wsrep%';

The output shows that the new node has been successfully added to the cluster. Cluster size is now 3 nodes, it is the primary component, and it is fully connected and ready to receive write-set replication.

| | ++ | |
|---------------------------------------|---------------------------------------|--|
| Variable_name | Value | |
| | ++ | |
| wsrep_local_state_uuid | c2883338-834d-11e2-0800-03c9c68e41ec | |
| | | |
| wsrep_local_state | 4 | |
| <pre>wsrep_local_state_comment</pre> | Synced | |
| | ···· | |
| wsrep cluster size | 3 | |
| wsrep cluster status | Primary | |
| wsrep connected | ON | |
| · _ | · · · · · · · · · · · · · · · · · · · | |
| wsrep ready | ON I | |
| · · · · · · · · · · · · · · · · · · · | ++ | |

6.9.3 Next steps

When you add all nodes to the cluster, you can verify replication by running queries and manipulating data on nodes to see if these changes are synchronized across the cluster.

Last update: 2023-07-21

6.10 Verify replication

Use the following procedure to verify replication by creating a new database on the second node, creating a table for that database on the third node, and adding some records to the table on the first node.

1. Create a new database on the second node:

mysql@pxc2> CREATE DATABASE percona;

The following output confirms that a new database has been created:

Expected output 🗡

```
Query OK, 1 row affected (0.01 sec)
```

2. Switch to a newly created database:

mysql@pxc3> USE percona;

The following output confirms that a database has been changed:

Expected output Y Database changed

3. Create a table on the third node:

mysql@pxc3> CREATE TABLE example (node_id INT PRIMARY KEY, node_name VARCHAR(30));

The following output confirms that a table has been created:

| Expected output ➤ | |
|--------------------------------------|--|
| Query OK, 0 rows affected (0.05 sec) | |

4. Insert records on the first node:

mysql@pxcl> INSERT INTO percona.example VALUES (1, 'perconal');

The following output confirms that the records have been inserted:

Expected output Y

Query OK, 1 row affected (0.02 sec)

5. Retrieve rows from that table on the second node:

```
mysql@pxc2> SELECT * FROM percona.example;
```

The following output confirms that all the rows have been retrieved:

| Expected output \checkmark | | |
|------------------------------|--|--|
| | | |
| ++ | | |
| node_id node_name | | |
| ++ | | |
| 1 perconal | | |
| ++ | | |
| 1 row in set (0.00 sec) | | |

6.10.1 Next steps

- Consider installing ProxySQL on client nodes for efficient workload management across the cluster without any changes to the applications that generate queries. This is the recommended high-availability solution for Percona XtraDB Cluster. For more information, see Load balancing with ProxySQL.
- Percona Monitoring and Management is the best choice for managing and monitoring Percona XtraDB Cluster performance. It provides visibility for the cluster and enables efficient troubleshooting.

7. Upgrade

7.1 Upgrade Percona XtraDB Cluster

The following documents contain details about relevant changes in the 8.0 series of MySQL and Percona Server for MySQL. Make sure you deal with any incompatible features and variables mentioned in these documents when upgrading to Percona XtraDB Cluster 8.0.

- Upgrading MySQL
- Upgrading from MySQL 5.7 to 8.0

7.1.1 Important changes in Percona XtraDB Cluster 8.0

- Upgrade Percona XtraDB Cluster
- Important changes in Percona XtraDB Cluster 8.0
- Traffic encryption is enabled by default
- Not recommended to mix PXC 5.7 nodes with PXC 8.0 nodes
- PXC strict mode is enabled by default
- The configuration file layout has changed in PXC 8.0
- caching_sha2_password is the default authentication plugin
- mysql_upgrade is part of SST
- Major upgrade scenarios
- Scenario: No active parallel workload or with read-only workload
- Scenario: Upgrade from PXC 5.6 to PXC 8.0
- Minor upgrade

Traffic encryption is enabled by default

The pxc_encrypt_cluster_traffic variable, which enables traffic encryption, is set to ON by default in Percona XtraDB Cluster 8.0.

Unless you configure a node accordingly (each node in your cluster must use the same SSL certificates) or try to join a cluster running PXC 5.7 which unencrypted cluster traffic, the node will not be able to join resulting in an error.

The error message

```
... [ERROR] ... [Galera] handshake with remote endpoint ... This error is often caused by SSL issues. ...
```

🖍 🖍 See also

sections Encrypting PXC Traffic, Configuring Nodes for Write-Set Replication

Not recommended to mix PXC 5.7 nodes with PXC 8.0 nodes

Shut down the cluster and upgrade each node to PXC 8.0. It is important that you make backups before attempting an upgrade.

PXC strict mode is enabled by default

Percona XtraDB Cluster in 8.0 runs with PXC Strict Mode enabled by default. This will deny any unsupported operations and may halt the server if a strict mode validation fails. It is recommended to first start the node with the pxc_strict_mode variable set to PERMISSIVE in the MySQL configuration file.

All configuration settings are stored in the default MySQL configuration file:

- Path on Debian and Ubuntu: /etc/mysql/mysql.conf.d/mysqld.cnf
- Path on Red Hat and CentOS: /etc/my.cnf

After you check the log for any tech preview features or unsupported features and you have fixed any of the encountered incompatibilities, set the variable back to ENFORCING at run time:

mysql> SET pxc_strict_mode=ENFORCING;

Restarting the node with the updated configuration file also sets variable to ENFORCING.

The configuration file layout has changed in PXC 8.0

All configuration settings are stored in the default MySQL configuration file:

- Path on Debian and Ubuntu: /etc/mysql/mysql.conf.d/mysqld.cnf
- Path on Red Hat and CentOS: /etc/my.cnf

Before you start the upgrade, move your custom settings from /etc/mysql/percona-xtradb-cluster.conf.d/ wsrep.cnf (on Debian and Ubuntu) or from /etc/percona-xtradb-cluster.conf.d/wsrep.cnf (on Red Hat and CentOS) to the new location accordingly.

🖍 Note

If you have moved your my.cnf file to a different location and added a symlink to /etc/my.cnf, the RPM package manager, when upgrading, can delete the symlink and put a default my.cnf file in /etc/.

caching_sha2_password is the default authentication plugin

In Percona XtraDB Cluster 8.0, the default authentication plugin is caching_sha2_password. The ProxySQL
option -syncusers will not work if the Percona XtraDB Cluster user is created using caching_sha2_password.
Use the mysql_native_password authentication plugin in these cases.

Be sure you are running on the latest 5.7 version before you upgrade to 8.0.

mysql_upgrade is part of SST

mysql_upgrade is now run automatically as part of SST. You do not have to run it manually when upgrading your system from an older version.

7.1.2 Major upgrade scenarios

Upgrading PXC from 5.7 to 8.0 may have slightly different strategies depending on the configuration and workload on your PXC cluster.

Note that the new default value of pxc-encrypt-cluster-traffic (set to ON versus OFF in PXC 5.7) requires additional care. You cannot join a 5.7 node to a PXC 8.0 cluster unless the node has traffic encryption enabled as the cluster may not have some nodes with traffic encryption enabled and some nodes with traffic encryption disabled. For more information, see Traffic encryption is enabled by default.

Scenario: No active parallel workload or with read-only workload

If there is no active parallel workload or the cluster has read-only workload while upgrading the nodes, complete the following procedure for each node in the cluster:

- 1. Shutdown one of the node 5.7 cluster nodes.
- 2. Remove 5.7 PXC packages without removing the data-directory.
- 3. Install PXC 8.0 packages.
- 4. Restart the mysqld service.

🗴 Important

Before upgrading, make sure your application can work with a reduced cluster size. If the cluster operates with an even number of nodes, the cluster may have split-brain.

This upgrade flow auto-detects the presence of the 5.7 data directory and trigger the upgrade as part of the node bootup process. The data directory is upgraded to be compatible with PXC 8.0. Then the node joins the cluster and enters synced state. The 3-node cluster is restored with 2 nodes running PXC 5.7 and 1 node running PXC 8.0.

🖍 Note

Since SST is not involved, SST based auto-upgrade flow is not started.

PXC 8.0 uses Galera 4 while PXC 5.7 uses Galera-3. The cluster will continue to use the protocol version 3 used in Galera 3 effectively limiting some of the functionality. With all nodes upgraded to version 8.0, protocol version 4 is applied.

| 🖍 Тір |
|---|
| The protocol version is stored in the protocol_version column of the wsrep_cluster table. |
| <pre>mysql> USE mysql;</pre> |
| <pre>mysql> SELECT protocol_version from wsrep_cluster;</pre> |
| The example of the output is the following: |
| ++
 protocol_version
++
 4
++
1 row in set (0.00 sec) |
| |

As soon as the last 5.7 node shuts down, the configuration of the remaining two nodes is updated to use protocol version 4. A new upgraded node will then join using protocol version 4 and the whole cluster will maintain protocol version 4 enabling the support for additional Galera 4 facilities.

It may take longer to join the last upgraded node since it will invite IST to obtain the configuration changes.

Starting from Galera 4, the configuration changes are cached to gcache and the configuration changes are donated as part of IST or SST to help build the certification queue on the JOINING node. As other nodes (say n2 and n3), already using protocol version 4, donate the configuration changes when the JOINER node is booted.

The situation was different for the previous and penultimate nodes since the donation of the configuration changes is not supported by protocol version 3 that they used.

With IST involved on joining the last node, the smart IST flow is triggered to take care of the upgrade even before MySQL starts to look at the data directory.

🗴 Important

It is not recommended to restart the last node without upgrading it.

Scenario: Upgrade from PXC 5.6 to PXC 8.0

First, upgrade PXC from 5.6 to the latest version of PXC 5.7. Then proceed with the upgrade using the procedure described in Scenario: No active parallel workload or with read-only workload.

7.1.3 Minor upgrade

To upgrade the cluster, follow these steps for each node:

- 1. Make sure that all nodes are synchronized.
- 2. Stop the mysql service:

\$ sudo service mysql stop

- 3. Upgrade Percona XtraDB Cluster and Percona XtraBackup packages. For more information, see Installing Percona XtraDB Cluster.
- 4. Back up grastate.dat, so that you can restore it if it is corrupted or zeroed out due to network issue.
- 5. Now, start the cluster node with 8.0 packages installed, PXC will upgrade the data directory as needed either as part of the startup process or a state transfer (IST/SST).

In most cases, starting the mysql service should run the node with your previous configuration. For more information, see Adding Nodes to Cluster.

\$ sudo service mysql start

🧪 Note

On CentOS, the /etc/my.cnf configuration file is renamed to my.cnf.rpmsave. Make sure to rename it back before joining the upgraded node back to the cluster.

PXC Strict Mode is enabled by default, which may result in denying any unsupported operations and may halt the server. For more information, see pxc-strict-mode is enabled by default.

pxc-encrypt-cluster-traffic is enabled by default. You need to configure each node accordingly and avoid joining a cluster with unencrypted cluster traffic. For more information, see Traffic encryption is enabled by default.

6. Repeat this procedure for the next node in the cluster until you upgrade all nodes.

Last update: 2023-07-21

7.2 Restore a 5.7 backup to an 8.0 cluster

Use Percona XtraBackup to back up the source server data and restore the data to a target server, and then upgrade the server to a different version of Percona XtraDB Cluster.

Downgrading is not supported.

7.2.1 Restore a database with a different server version

Review Upgrade Percona XtraDB cluster.

Upgrade the nodes one at a time. The primary node should be the last node to be upgraded. The following steps are required on each node.

- 1. Back up the data on the source server.
- 2. Install the same database version as the source server on the target server.
- 3. Restore with a copy-back operation on the target server.
- 4. Start the database server on the target server.
- 5. Do a slow shutdown of the database server with the SET GLOBAL innodb_fast_shutdown=0 statement. This shutdown type flushes InnoDB operations before completing and may take longer.
- 6. Install the new database server version on the target server.
- 7. Start the new database server version on the restored data directory.
- 8. Perform any other upgrade steps as necessary.

To ensure the upgrade was successful, check the data.

8. PXC security

8.1 Security basics

By default, Percona XtraDB Cluster does not provide any protection for stored data. There are several considerations to take into account for securing Percona XtraDB Cluster:

• Securing the Network

Anyone with access to your network can connect to any Percona XtraDB Cluster node either as a client or as another node joining the cluster. You should consider restricting access using VPN and filter traffic on ports used by Percona XtraDB Cluster.

• Encrypting PXC Traffic

Unencrypted traffic can potentially be viewed by anyone monitoring your network. In Percona XtraDB Cluster 8.0 traffic encryption is enabled by default.

Data-at-rest encryption

Percona XtraDB Cluster supports tablespace encryption to provide at-rest encryption for physical tablespace data files.

For more information, see the following blog post:

```
* [MySQL Data at Rest Encryption](https://www.percona.com/blog/2016/04/08/mysql-data-at-
rest-encryption/)
```

8.1.1 Security modules

Most modern distributions include special security modules that control access to resources for users and applications. By default, these modules will most likely constrain communication between Percona XtraDB Cluster nodes.

The easiest solution is to disable or remove such programs, however, this is not recommended for production environments. You should instead create necessary security policies for Percona XtraDB Cluster.

SELinux

SELinux is usually enabled by default in Red Hat Enterprise Linux and derivatives (including CentOS). SELinux helps protects the user's home directory data and provides the following:

- Prevents unauthorized users from exploiting the system
- Allows authorized users to access files
- Used as a role-based access control system

To help with troubleshooting, during installation and configuration, you can set the mode to permissive:

setenforce 0

🖍 Note

This action changes the mode only at runtime.

See also

For more information, see Enabling AppArmor

AppArmor

AppArmor is included in Debian and Ubuntu. *Percona XtraDB Cluster* contains several AppArmor profiles which allows for easier maintenance. To help with troubleshooting, during the installation and configuration, you can set the mode to complain for mysqld.

Last update: 2023-07-21

8.2 Secure the network

By default, anyone with access to your network can connect to any Percona XtraDB Cluster node either as a client or as another node joining the cluster. This could potentially let them query your data or get a complete copy of it.

In general, it is a good idea to disable all remote connections to Percona XtraDB Cluster nodes. If you require clients or nodes from outside of your network to connect, you can set up a VPN (virtual private network) for this purpose.

8.2.1 Firewall configuration

A firewall can let you filter Percona XtraDB Cluster traffic based on the clients and nodes that you trust.

By default, Percona XtraDB Cluster nodes use the following ports:

- 3306 is used for MySQL client connections and SST (State Snapshot Transfer) via mysqldump.
- 4444 is used for SST via Percona XtraBackup.
- 4567 is used for write-set replication traffic (over TCP) and multicast replication (over TCP and UDP).
- 4568 is used for IST (Incremental State Transfer).

Ideally you want to make sure that these ports on each node are accessed only from trusted IP addresses. You can implement packet filtering using iptables, firewalld, pf, or any other firewall of your choice.

Use iptables

To restrict access to Percona XtraDB Cluster ports using iptables, you need to append new rules to the INPUT chain on the filter table. In the following example, the trusted range of IP addresses is 192.168.0.1/24. It is assumed that only Percona XtraDB Cluster nodes and clients will connect from these IPs. To enable packet filtering, run the commands as root on each Percona XtraDB Cluster node.

```
# iptables --append INPUT --in-interface eth0 \
    --protocol tcp --match tcp --dport 3306 \
    --source 192.168.0.1/24 --jump ACCEPT
# iptables --append INPUT --in-interface eth0 \
```

```
--protocol tcp --match tcp --dport 4444 \
--source 192.168.0.1/24 --jump ACCEPT
# iptables --append INPUT --in-interface eth0 \
--protocol tcp --match tcp --dport 4567 \
--source 192.168.0.1/24 --jump ACCEPT
# iptables --append INPUT --in-interface eth0 \
--protocol tcp --match tcp --dport 4568 \
--source 192.168.0.1/24 --jump ACCEPT
# iptables --append INPUT --in-interface eth0 \
--protocol udp --match udp --dport 4567 \
--source 192.168.0.1/24 --jump ACCEPT
```

🖍 Note

The last one opens port 4567 for multicast replication over UDP.

If the trusted IPs are not in sequence, you will need to run these commands for each address on each node. In this case, you can consider to open all ports between trusted hosts. This is a little bit less secure, but reduces the amount of commands. For example, if you have three Percona XtraDB Cluster nodes, you can run the following commands on each one:

```
# iptables --append INPUT --protocol tcp \
    --source 64.57.102.34 --jump ACCEPT
# iptables --append INPUT --protocol tcp \
    --source 193.166.3.20 --jump ACCEPT
# iptables --append INPUT --protocol tcp \
    --source 193.125.4.10 --jump ACCEPT
```

Running the previous commands will allow TCP connections from the IP addresses of the other Percona XtraDB Cluster nodes.

🖍 Note

The changes that you make in iptables are not persistent unless you save the packet filtering state:

```
# service save iptables
```

For distributions that use systemd, you need to save the current packet filtering rules to the path where iptables reads from when it starts. This path can vary by distribution, but it is usually in the /etc directory. For example:

- /etc/sysconfig/iptables
- /etc/iptables/iptables.rules

Use iptables-save to update the file:

```
# iptables-save > /etc/sysconfig/iptables
```

Last update: 2023-07-21

8.3 Encrypt PXC traffic

There are two kinds of traffic in Percona XtraDB Cluster:

- 1. Client-server traffic (the one between client applications and cluster nodes),
- 2. Replication traffic, that includes SST, IST, write-set replication, and various service messages.

Percona XtraDB Cluster supports encryption for all types of traffic. Replication traffic encryption can be configured either automatically or manually.

8.3.1 Encrypt client-server communication

Percona XtraDB Cluster uses the underlying MySQL encryption mechanism to secure communication between client applications and cluster nodes.

MySQL generates default key and certificate files and places them in the data directory. You can override auto-generated files with manually created ones, as described in the section Generate keys and certificates manually.

The auto-generated files are suitable for automatic SSL configuration, but you should use the same key and certificate files on all nodes.

Specify the following settings in the my.cnf configuration file for each node:

```
[mysqld]
ssl-ca=/etc/mysql/certs/ca.pem
ssl-cert=/etc/mysql/certs/server-cert.pem
ssl-key=/etc/mysql/certs/server-key.pem
[client]
ssl-ca=/etc/mysql/certs/ca.pem
ssl-cert=/etc/mysql/certs/client-cert.pem
ssl-key=/etc/mysql/certs/client-key.pem
```

After it is restarted, the node uses these files to encrypt communication with clients. MySQL clients require only the second part of the configuration to communicate with cluster nodes.

MySQL generates the default key and certificate files and places them in the data directory. You can either use them or generate new certificates. For generation of new certificate please refer to Generate keys and certificates manually section.

8.3.2 Encrypt replication traffic

Replication traffic refers to the inter-node traffic which includes the SST traffic, IST traffic, and replication traffic.

The traffic of each type is transferred via a different channel, and so it is important to configure secure channels for all 3 variants to completely secure the replication traffic.

Percona XtraDB Cluster supports a single configuration option which helps to secure the complete replication traffic, and is often referred to as SSL automatic configuration. You can also configure the security of each channel by specifying independent parameters.

8.3.3 SSL automatic configuration

The automatic configuration of the SSL encryption needs a key and certificate files. MySQL generates a default key and certificate files and places them in the data directory.

Important

It is important that your cluster use the same SSL certificates on all nodes.

Enable pxc-encrypt-cluster-traffic

Percona XtraDB Cluster includes the pxc-encrypt-cluster-traffic variable that enables automatic configuration of SSL encryption there-by encrypting SST, IST, and replication traffic.

By default, pxc-encrypt-cluster-traffic is enabled thereby using a secured channel for replication. This variable is not dynamic and so it cannot be changed at runtime.

Enabled, pxc-encrypt-cluster-traffic has the effect of applying the following settings: encrypt, ssl_key, ssl-ca, ssl-cert.

Setting pxc-encrypt-cluster-traffic=ON has the effect of applying the following settings in the my.cnf configuration file:

```
[mysqld]
wsrep_provider_options="socket.ssl_key=server-key.pem;socket.ssl_cert=server-
cert.pem;socket.ssl_ca=ca.pem"
[sst]
encrypt=4
ssl-key=server-key.pem
ssl-ca=ca.pem
ssl-ca=ca.pem
```

For wsrep_provider_options, only the mentioned options are affected (socket.ssl_key, socket,ssl_cert, and socket.ssl_ca), the rest is not modified.

Important

Disabling pxc-encrypt-cluster-traffic

The default value of pxc-encrypt-cluster-traffic helps improve the security of your system.

When pxc-encrypt-cluster-traffic is not enabled, anyone with the access to your network can connect to any PXC node either as a client or as another node joining the cluster. This potentially lets them query your data or get a complete copy of it.

If you must disable pxc-encrypt-cluster-traffic, you need to stop the cluster and update [mysqld] section of the configuration file: pxc-encrypt-cluster-traffic=0FF of each node. Then, restart the cluster.

The automatic configuration of the SSL encryption needs key and certificate files. MySQL generates default key and certificate files and places them in data directory. These auto-generated files are suitable for automatic SSL configuration, but *you should use the same key and certificate files on all nodes*. Also you can override auto-generated files with manually created ones, as covered in Generate keys and certificates manually.

The necessary key and certificate files are first searched at the ssl-ca, ssl-cert, and ssl-key options under [mysqld]. If these options are not set, the data directory is searched for ca.pem, server-cert.pem, and server-key.pem files.

Note

The [sst] section is not searched.

If all three files are found, they are used to configure encryption. If any of the files is missing, a fatal error is generated.

8.3.4 SSL manual configuration

If user wants to enable encryption for specific channel only or use different certificates or other mix-match, then user can opt for manual configuration. This helps to provide more flexibility to end-users.

To enable encryption manually, the location of the required key and certificate files shoud be specified in the Percona XtraDB Cluster configuration. If you do not have the necessary files, see Generate keys and certificates manually.

Encryption settings are not dynamic. To enable it on a running cluster, you need to restart the entire cluster.

There are three aspects of Percona XtraDB Cluster operation, where you can enable encryption:

• Encrypt SST traffic

This refers to SST traffic during full data copy from one cluster node (donor) to the joining node (joiner).

- Encrypt replication traffic
- Encrypt IST traffic

This refers to all internal Percona XtraDB Cluster communication, such as, write-set replication, IST, and various service messages.

Encrypt SST traffic

This refers to full data transfer that usually occurs when a new node (JOINER) joins the cluster and receives data from an existing node (DONOR).

For more information, see State snapshot transfer.

If keyring_file plugin is used, then SST encryption is mandatory: when copying encrypted data via SST, the keyring must be sent over with the files for decryption. In this case following options are to be set in my.cnf on all nodes:

74 of 240

```
early-plugin-load=keyring_file.so
keyring-file-data=/path/to/keyring/file
```

The cluster will not work if keyring configuration across nodes is different.

The only available SST method is xtrabackup-v2 which uses Percona XtraBackup.

xtrabackup

This is the only available SST method (the wsrep_sst_method is always set to xtrabackup-v2), which uses Percona XtraBackup to perform non-blocking transfer of files. For more information, see Percona XtraBackup SST Configuration.

Encryption mode for this method is selected using the encrypt option:

- encrypt=0 is the default value, meaning that encryption is disabled.
- encrypt=4 enables encryption based on key and certificate files generated with OpenSSL. For more information, see Generating Keys and Certificates Manually.

To enable encryption for SST using XtraBackup, specify the location of the keys and certificate files in the each node's configuration under [sst]:

```
[sst]
encrypt=4
ssl-ca=/etc/mysql/certs/ca.pem
ssl-cert=/etc/mysql/certs/server-cert.pem
ssl-key=/etc/mysql/certs/server-key.pem
```

🧪 Note

SSL clients require DH parameters to be at least 1024 bits, due to the logjam vulnerability. However, versions of socat earlier than 1.7.3 use 512-bit parameters. If a dhparams.pem file of required length is not found during SST in the data directory, it is generated with 2048 bits, which can take several minutes. To avoid this delay, create the dhparams.pem file manually and place it in the data directory before joining the node to the cluster:

openssl dhparam -out /path/to/datadir/dhparams.pem 2048

For more information, see this blog post.

Encrypt replication/IST traffic

Replication traffic refers to the following:

- Write-set replication which is the main workload of Percona XtraDB Cluster (replicating transactions that execute on one node to all other nodes).
- Incremental State Transfer (IST) which is copying only missing transactions from DONOR to JOINER node.
- · Service messages which ensure that all nodes are synchronized.

All this traffic is transferred via the same underlying communication channel (gcomm). Securing this channel will ensure that IST traffic, write-set replication, and service messages are encrypted. (For IST, a separate channel is configured using the same configuration parameters, so 2 sections are described together).

To enable encryption for all these processes, define the paths to the key, certificate and certificate authority files using the following wsrep provider options:

- socket.ssl_ca
- socket.ssl_cert
- socket.ssl_key

To set these options, use the wsrep_provider_options variable in the configuration file:

```
wsrep_provider_options="socket.ssl=yes;socket.ssl_ca=/etc/mysql/certs/
ca.pem;socket.ssl_cert=/etc/mysql/certs/server-cert.pem;socket.ssl_key=/etc/mysql/certs/
server-key.pem"
```

🖍 Note

You must use the same key and certificate files on all nodes, preferably those used for Encrypt client-server communication.

Check upgrade-certificate section on how to upgrade existing certificates.

8.3.5 Generate keys and certificates manually

As mentioned above, MySQL generates default key and certificate files and places them in the data directory. If you want to override these certificates, the following new sets of files can be generated:

- Certificate Authority (CA) key and certificate to sign the server and client certificates.
- Server key and certificate to secure database server activity and write-set replication traffic.
- Client key and certificate to secure client communication traffic.

These files should be generated using OpenSSL.

Note

The Common Name value used for the server and client keys and certificates must differ from that value used for the CA certificate.

Generate CA key and certificate Generate server key and certificate Generate client key and certificate

The Certificate Authority is used to verify the signature on certificates.

1. Generate the CA key file:

\$ openssl genrsa 2048 > ca-key.pem

2. Generate the CA certificate file:

1. Generate the server key file:

2. Remove the passphrase:

\$ openssl rsa -in server-key.pem -out server-key.pem

3. Generate the server certificate file:

```
$ openssl x509 -req -in server-req.pem -days 3600 \
    -CA ca.pem -CAkey ca-key.pem -set_serial 01 \
    -out server-cert.pem
```

1. Generate the client key file:

2. Remove the passphrase:

\$ openssl rsa -in client-key.pem -out client-key.pem

3. Generate the client certificate file:

```
$ openssl x509 -req -in client-req.pem -days 3600 \
    -CA ca.pem -CAkey ca-key.pem -set_serial 01 \
    -out client-cert.pem
```

Verify certificates

To verify that the server and client certificates are correctly signed by the CA certificate, run the following command:

\$ openssl verify -CAfile ca.pem server-cert.pem client-cert.pem

If the verification is successful, you should see the following output:

server-cert.pem: OK
client-cert.pem: OK

Failed validation caused by matching CN

Sometimes, an SSL configuration may fail if the certificate and the CA files contain the same .

To check if this is the case run openssl command as follows and verify that the **CN** field differs for the *Subject* and *Issuer* lines.

\$ openssl x509 -in server-cert.pem -text -noout

Incorrect values

```
Certificate:
Data:
Version: 1 (0x0)
Serial Number: 1 (0x1)
Signature Algorithm: sha256WithRSAEncryption
Issuer: CN=www.percona.com, 0=Database Performance., C=US
...
Subject: CN=www.percona.com, 0=Database Performance., C=AU
...
```

To obtain a more compact output run opensil specifying -subject and -issuer parameters:

\$ openssl x509 -in server-cert.pem -subject -issuer -noout

Expected output

subject= /CN=www.percona.com/0=Database Performance./C=AU
issuer= /CN=www.percona.com/0=Database Performance./C=US

Deploy keys and certificates

Use a secure method (for example, scp or sftp) to send the key and certificate files to each node. Place them under the /etc/mysql/certs/ directory or similar location where you can find them later.

🧪 Note

Make sure that this directory is protected with proper permissions. Most likely, you only want to give read permissions to the user running <code>mysqld</code>.

The following files are required:

• Certificate Authority certificate file (ca.pem)

This file is used to verify signatures.

• Server key and certificate files (server-key.pem and server-cert.pem)

These files are used to secure database server activity and write-set replication traffic.

• Client key and certificate files (client-key.pem and client-cert.pem)

These files are required only if the node should act as a MySQL client. For example, if you are planning to perform SST using mysqldump.

🖍 Note

Upgrade certificates subsection covers the details on upgrading certificates, if necessary.

Upgrade certificates

The following procedure shows how to upgrade certificates used for securing replication traffic when there are two nodes in the cluster.

1. Restart the first node with the socket.ssl_ca option set to a combination of the the old and new certificates in a single file.

For example, you can merge contents of old-ca.pem and new-ca.pem into upgrade-ca.pem as follows:

cat old-ca.pem > upgrade-ca.pem && \
cat new-ca.pem >> upgrade-ca.pem

Set the wsrep_provider_options variable as follows:

```
wsrep_provider_options="socket.ssl=yes;socket.ssl_ca=/etc/mysql/certs/upgrade-
ca.pem;socket.ssl_cert=/etc/mysql/certs/old-cert.pem;socket.ssl_key=/etc/mysql/certs/old-
key.pem"
```

2. Restart the second node with the socket.ssl_ca, socket.ssl_cert, and socket.ssl_key options set to the corresponding new certificate files.

```
wsrep_provider_options="socket.ssl=yes;socket.ssl_ca=/etc/mysql/certs/new-
ca.pem;socket.ssl_cert=/etc/mysql/certs/new-cert.pem;socket.ssl_key=/etc/mysql/certs/new-
key.pem"
```

- 3. Restart the first node with the new certificate files, as in the previous step.
- 4. You can remove the old certificate files.

Last update: 2023-07-21

8.4 Enable AppArmor

Percona XtraDB Cluster contains several AppArmor profiles. Multiple profiles allow for easier maintenance because the mysqld profile is decoupled from the SST script profile. This separation allows the introduction of other SST methods or scripts with their own profiles.

The following profiles are available:

- An extended version of the Percona Server profile which allows the execution of SST script.
- An xtrabackup-v2 SST script profile located in /etc/apparmor.d/usr.bin.wsrep_sst_xtrabackup-v2

The mysqld profile allows the execution of the SST script in PUx mode with the /{usr/}bin/wsrep_sst_*PUx command. The profile is applied if the script contains a profile. The SST script runs in unconfined mode if the script does not contain a profile. The system administrator can change the execution mode to Pix. This action causes a fallback to inherited mode in case the SST script profile is absent.

8.4.1 Profile adjustments

The mysqld profile and the SST script profile can be adjusted, such as moving the data directory, in the same way as modifying the mysqld profile in Percona Server.

8.4.2 Work with pxc_encrypt_cluster_traffic

By default, the pxc_encrypt_cluster_traffic is ON, which means that all cluster traffic is protected with certificates. However, these certificates cannot be located in the data directory since that location is overwritten during the SST process.

Set up the certificates describes the certificate setup.

The following AppArmor profile rule grants access to certificates located in /etc/mysql/certs. You must be root or have sudo privileges.

```
# Allow config access
   /etc/mysql/** r,
```

This rule is present in both profiles (usr.sbin.mysqld and usr.bin.wsrep_sst_xtrabackup-v2). The rule allows the administrator to store the certificates anywhere inside of the /etc/mysql/ directory. If the certificates are located outside of the specified directory, you must add an additional rule which allows access to the certificates in both profiles. The rule must have the path to the certificates location, like the following:

```
# Allow config access
/path/to/certificates/* r,
```

The server certificates must be accessible to the mysql user and are readable only by this user.

Last update: 2023-07-21

8.5 Enable SELinux

SELinux helps protects the user's home directory data. SELinux provides the following:

- Prevents unauthorized users from exploiting the system
- · Allows authorized users to access files
- Used as a role-based access control system

For more information, see Percona Server and SELinux

Red Hat and CentOS distributes a policy module to extend the SELinux policy module for mysqld. We provide the following:

- Extended module for pxc an extension of the default module for mysqld distributed by the operating system.
- wsrep-sst-xtrabackup-v2 allows execution of the xtrabackup-v2 SST script

8.5.1 Modify policies

Modifications described in Percona Server and SELinux can also be applied for Percona XtraDB Cluster.

To adjust PXC-specific configurations, especially SST/IST ports, use the following procedures as root:

To enable port 14567 instead of the default port 4567:

Find the tag associated with the 4567 port:

\$ semanage port -l | grep 4567 tram_port_t tcp 4567

Run a command to find which rules grant mysqld access to the port:

```
$ sesearch -A -s mysqld_t -t tram_port_t -c tcp_socket
Found 5 semantic av rules:
    allow mysqld_t port_type : tcp_socket { recv_msg send_msg } ;
    allow mysqld_t tram_port_t : tcp_socket { name_bind name_connect } ;
    allow mysqld_t port_type : tcp_socket { recv_msg send_msg } ;
    allow mysqld_t port_type : tcp_socket name_connect ;
    allow nsswitch_domain port_type : tcp_socket { recv_msg send_msg } ;
```

You could tag port 14567 with the tramp_port_t tag, but this tag may cause issues because port 14567 is not a TRAM port. Use the general mysqld_port_t tag to add ports. For example, the following command adds port 14567 to the policy module with the mysqld_port_t tag.

\$ semanage port -a -t mysqld port t -p tcp 14567

You can verify the addition with the following command:

```
$ semanage port -l | grep 14567
mysqld_port_t tcp 4568, 14567, 1186, 3306, 63132-63164
```

To see the tag associated with the 4444 port, run the following command:

| <pre>\$ semanage port -l grep 4444</pre> | ļ. | |
|--|-----|---------------|
| kerberos_port_t | tcp | 88, 750, 4444 |
| kerberos_port_t | udp | 88, 750, 4444 |

To find the rules associated with kerberos_port_t, run the following:

\$ sesearch -A -s mysqld_t -t kerberos_port_t -c tcp_socket Found 9 semantic av rules: allow mysqld_t port_type : tcp_socket { recv_msg send_msg } ; allow mysqld_t port_type : tcp_socket name_bind ; allow mysqld_t port_type : tcp_socket { recv_msg send_msg } ; allow mysqld_t port_type : tcp_socket name_connect ; allow nsswitch_domain kerberos_port_t : tcp_socket name_connect ; allow nsswitch_domain kerberos_port_t : tcp_socket { recv_msg send_msg } ; allow nsswitch_domain reserved_port_type : tcp_socket name_connect ; allow nsswitch_domain reserved_port_type : tcp_socket name_connect ; allow mysqld_t reserved_port_type : tcp_socket name_connect ; allow nsswitch_domain port_type : tcp_socket name_connect ;

If you require port 14444 added, use the same method used to add port 14567.

If you must use a port that is already tagged, you can use either of the following ways:

- Change the port tag to mysqld_port_t
- Adjust the mysqld/sst script policy module to allow access to the given port. This method is better since all PXC-related adjustments are within the PXC-related policy modules.

8.5.2 Work with pxc_encrypt_cluster_traffic

By default, the pxc_encrypt_cluster_traffic is 0N, which means that all cluster traffic is protected with certificates. However, these certificates cannot be located in the data directory since that location is overwritten during the SST process.

Review How to set up the certificates. When SELinux is enabled, mysqld must have access to these certificates. The following items must be checked or considered:

- Certificates inside /etc/mysql/certs/ directory must use the mysqld_etc_t tag. This tag is applied automatically when the files are copied into the directory. When they are moved, the files retain their original context.
- Certificates are accessible to the mysql user. The server certificates should be readable only by this user.
- Certificates without the proper SELinux context can be restored with the following command:

\$ restorecon -v /etc/mysql/certs/*

8.5.3 Enable enforcing mode for PXC

The process, mysqld, runs in permissive mode, by default, even if SELinux runs in enforcing mode:

```
$ semodule -l | grep permissive
permissive_mysqld_t
permissivedomains
```

After ensuring that the system journal does not list any issues, the administrator can remove the permissive mode for mysqld_t:

\$ semanage permissive -d mysqld_t

MariaDB 10.2 Galera Cluster with SELinux-enabled on CentOS 7

Last update: 2023-07-21

9. User's manual

9.1 State snapshot transfer

State Snapshot Transfer (SST) is a full data copy from one node (donor) to the joining node (joiner). It's used when a new node joins the cluster. In order to be synchronized with the cluster, the new node has to receive data from a node that is already part of the cluster.

Percona XtraDB Cluster enables via **xtrabackup**.

Xtrabackup SST uses backup locks, which means the Galera provider is not paused at all as with earlier. The SST method can be configured using the wsrep_sst_method variable.

🧪 Note

If the gcs.sync_donor variable is set to Yes (default is No), the whole cluster will get blocked if the donor is blocked by SST.

9.1.1 Choose the SST Donor

If there are no nodes available that can safely perform incremental state transfer (IST), the cluster defaults to SST.

If there are nodes available that can perform IST, the cluster prefers a local node over remote nodes to serve as the donor.

If there are no local nodes available that can perform IST, the cluster chooses a remote node to serve as the donor.

If there are several local and remote nodes that can perform IST, the cluster chooses the node with the highest seque to serve as the donor.

9.1.2 Use Percona Xtrabackup

The default SST method is xtrabackup-v2 which uses *Percona XtraBackup*. This is the least blocking method that leverages backup locks. XtraBackup is run locally on the donor node.

The datadir needs to be specified in the server configuration file <code>my.cnf</code>, otherwise the transfer process will fail.

Detailed information on this method is provided in Percona XtraBackup SST Configuration documentation.

9.1.3 SST for tables with tablespaces that are not in the data directory

For example:

CREATE TABLE t1 (c1 INT PRIMARY KEY) DATA DIRECTORY = '/alternative/directory';

SST using Percona XtraBackup

XtraBackup will restore the table to the same location on the joiner node. If the target directory does not exist, it will be created. If the target file already exists, an error will be returned, because XtraBackup cannot clear tablespaces not in the data directory.

9.1.4 Other reading

- State Snapshot Transfer Methods for MySQL
- Xtrabackup SST configuration

Last update: 2023-07-21

9.2 Percona XtraBackup SST configuration

Percona XtraBackup SST works in two stages:

- 1. First it identifies the type of data transfer based on the presence of xtrabackup_ist file on the joiner node.
- 2. Then it starts data transfer. In case of SST, it empties the data directory except for some files (galera.cache, sst_in_progress, grastate.dat) and then proceeds with SST.

In case of IST, it proceeds as before.

9.2.1 SST options

The following options specific to SST can be used in my.cnf under [sst].

- Non-integer options which have no default value are disabled if not set.
- :Match: Yes implies that option should match on donor and joiner nodes.
- SST script reads <code>my.cnf</code> when it runs on either donor or joiner node, not during <code>mysqld</code> startup.
- SST options must be specified in the main my.cnf file.

streamfmt

| Parameter | Description |
|-----------|-------------|
| Values: | xbstream |
| Default: | xbstream |
| Match: | Yes |

Used to specify the Percona XtraBackup streaming format. The only option is the xbstream format. SST fails and generates an error when another format, such as tar, is used.

For more information about the xbstream format, see The xbstream Binary.

transferfmt

ParameterDescriptionValues:socat , ncDefault:socatMatch:Yes

Used to specify the data transfer format. The recommended value is the default transferfmt=socat because it allows for socket options, such as transfer buffer sizes. For more information, see socat(1).

🖍 Note

Using transferfmt=nc does not support the SSL-based encryption mode (value 4 for the encrypt option).

ssl-ca

Example: ssl-ca=/etc/ssl/certs/mycert.crt

Specifies the absolute path to the certificate authority (CA) file for socat encryption based on OpenSSL.

ssl-cert

Example: ssl-cert=/etc/ssl/certs/mycert.pem

Specifies the full path to the certificate file in the PEM format for socat encryption based on OpenSSL.

For more information about ssl-ca and ssl-cert, see https://www.dest-unreach.org/socat/doc/socatopenssltunnel.html. The ssl-ca is essentially a self-signed certificate in that example, and ssl-cert is the PEM file generated after concatenation of the key and the certificate generated earlier. The names of options were chosen to be compatible with socat parameter names as well as with MySQL's SSL authentication. For testing you can also download certificates from launchpad.

🖍 Note

Irrespective of what is shown in the example, you can use the same .crt and .pem files on all nodes and it will work, since there is no server-client paradigm here, but rather a cluster with homogeneous nodes.

ssl-key

Example: ssl-key=/etc/ssl/keys/key.pem

Used to specify the full path to the private key in PEM format for socat encryption based on OpenSSL.

encrypt

| Parameter | Description |
|-----------|-------------|
| Values: | 0, 4 |
| Default: | 4 |
| Match: | Yes |

Enables SST encryption mode in Percona XtraBackup:

- Set encrypt=0 to disable SST encryption.
- Set encrypt=4 for SST encryption with SSL files generated by MySQL. This is the recommended value.

Considering that you have all three necessary files:

```
[sst]
encrypt=4
ssl-ca=ca.pem
ssl-cert=server-cert.pem
ssl-key=server-key.pem
```

For more information, see Encrypting PXC Traffic.

sockopt

Used to specify key/value pairs of socket options, separated by commas, for example:

```
[sst]
sockopt="retry=2,interval=3"
```

The previous example causes socat to try to connect three times (initial attempt and two retries with a 3second interval between attempts).

This option only applies when socat is used (transferfmt=socat). For more information about socket options, see socat (1).

🖍 Note

You can also enable SSL based compression with sockopt. This can be used instead of the Percona XtraBackup compress option.

ncsockopt

Used to specify socket options for the netcat transfer format (transferfmt=nc).

progress

Values: 1, path/to/file

Used to specify where to write SST progress. If set to 1, it writes to MySQL stderr. Alternatively, you can specify the full path to a file. If this is a FIFO, it needs to exist and be open on reader end before itself, otherwise wsrep_sst_xtrabackup will block indefinitely.

🖍 Note

Value of 0 is not valid.

rebuild

| Parameter | Description |
|-----------|-------------|
| Values: | 0, 1 |
| Default: | 0 |

Used to enable rebuilding of index on joiner node. This is independent of compaction, though compaction enables it. Rebuild of indexes may be used as an optimization.

🖍 Note

#1192834 affects this option.

time

| Parameter | Description |
|-----------|-------------|
| Values: | 0, 1 |
| Default: | 0 |

Enabling this option instruments key stages of backup and restore in SST.

rlimit

Example: rlimit=128k

Used to set a a ratelimit in bytes. Add a suffix (k, m, g, t) to specify units. For example, 128k is 128 kilobytes. For more information, see pv(1).

Rate is limited on donor node. The rationale behind this is to not allow SST to saturate the donor's regular cluster operations or to limit the rate for other purposes.

use_extra

| Parameter | Description |
|-----------|-------------|
| Values: | 0, 1 |
| Default: | 0 |

Used to force SST to use the thread pool's extra_port. Make sure that thread pool is enabled and the extra_port option is set in my.cnf before you enable this option.

cpat

```
Default: '.\*\\.pem$\\|.\*init\\.ok$\\|.\*galera\\.cache$\\|.\*sst_in_progress$\\|.\*\\.sst$\\|.
\*gvwstate\\.dat$\\|.\*grastate\\.dat$\\|.\*\\.log$\\|.\*RPM_UPGRADE_MARKER$\\|.
\*RPM_UPGRADE_HISTORY$'
```

Used to define the files that need to be retained in the datadir before running SST, so that the state of the other node can be restored cleanly.

For example:

```
[sst]
cpat='.*galera\.cache$\|.*sst_in_progress$\|.*grastate\.dat$\|.*\.err$\|.*\.log$
\|.*RPM_UPGRADE_MARKER$\|.*RPM_UPGRADE_HISTORY$\|.*\.xyz$'
```

Note

This option can only be used when wsrep_sst_method is set to xtrabackup-v2 (which is the default value).

compressor

| Parameter | Description |
|-----------|--------------------------|
| Default: | not set (disabled) |
| Example: | compressor='zstd -T0 -2' |

decompressor

| Parameter | Description |
|-----------|-----------------------------|
| Default: | not set (disabled) |
| Example: | decompressor='zstd -T0 -dc' |

Stream-based compression and decompression are performed on the stream, in contrast to performing decompression after streaming to disk, which involves additional I/O. The savings are considerable, up to half the I/O on the JOINER node.

You can use any compression utility which works on stream: gzip, pigz, zstd, and others. The pigz or zstd options are multi-threaded. At a minimum, the compressor must be set on the DONOR and the decompressor on JOINER.

You must install the related binaries, otherwise SST aborts.

compressor='pigz' decompressor='pigz -dc'

compressor='gzip' decompressor='gzip -dc'

To revert to the XtraBackup-based compression, set compress under [xtrabackup]. You can define both the compressor and the decompressor, although you will be wasting CPU cycles.

[xtrabackup]
compress
-- compact has led to some crashes

inno-backup-opts

inno-apply-opts

inno-move-opts

| Parameter | Description |
|-----------|---------------|
| Default: | Empty |
| Туре: | Quoted String |

This group of options is used to pass XtraBackup options for backup, apply, and move stages. The SST script doesn't alter, tweak, or optimize these options.

Note

Although these options are related to XtraBackup SST, they cannot be specified in <code>my.cnf</code>, because they are for passing innobackupex options.

sst-initial-timeout

| Parameter | Description |
|-----------|-------------|
| Default: | 100 |
| Unit: | seconds |

This option is used to configure initial timeout (in seconds) to receive the first packet via SST. This has been implemented, so that if the donor node fails somewhere in the process, the joiner node will not hang up and wait forever.

By default, the joiner node will not wait for more than 100 seconds to get a donor node. The default should be sufficient, however, it is configurable, so you can set it appropriately for your cluster. To disable initial SST timeout, set sst-initial-timeout=0.

/ Note

If you are using wsrep_sst_donor, and you want the joiner node to strictly wait for donors listed in the variable and not fall back (that is, without a terminating comma at the end), **and** there is a possibility of **all** nodes in that variable to be unavailable, disable initial SST timeout or set it to a higher value (maximum threshold that you want the joiner node to wait). You can also disable this option (or set it to a higher value) if you believe all other nodes in the cluster can potentially become unavailable at any point in time (mostly in small clusters) or there is a high network latency or network disturbance (which can cause donor selection to take longer than 100 seconds).

sst-idle-timeout

| Parameter | Description |
|-----------|-------------|
| Default: | 120 |
| Unit: | seconds |

This option configures the time the SST operation waits on the joiner to receive more data. The size of the joiner's sst directory is checked for the amount of data received. For example, the directory has received 50MB of data. The operation rechecks the data size after the default value, 120 seconds, has elapsed. If the data size is still 50MB, this operation is aborted. If the data has increased, the operation continues.

An example of setting the option:

```
[sst]
sst-idle-timeout=0
```

tmpdir

| Parameter | Description |
|-----------|-------------|
| Default: | Empty |

| Parameter | Description |
|-----------|------------------|
| Unit: | /path/to/tmp/dir |

This option specifies the location for storing the temporary file on a donor node where the transaction log is stored before streaming or copying it to a remote host.

/ Note

This option can be used on joiner node to specify non-default location to receive temporary SST files. This location must be large enough to hold the contents of the entire database. If tmpdir is empty then default location datadir/.sst will be used.

The tmpdir option can be set in the following my.cnf groups:

- [sst] is the primary location (others are ignored)
- [xtrabackup] is the secondary location (if not specified under [sst])
- [mysqld] is used if it is not specified in either of the above

wsrep_debug

Specifies whether additional debugging output for the database server error log should be enabled. Disabled by default.

This option can be set in the following my.cnf groups:

- Under [mysqld] it enables debug logging for mysqld and the SST script
- Under [sst] it enables debug logging for the SST script only

encrypt_threads

| Parameter | Description |
|-----------|-------------|
| Default: | 4 |

Specifies the number of threads that XtraBackup should use for encrypting data (when encrypt=1). The value is passed using the --encrypt-threads option in XtraBackup.

This option affects only SST with XtraBackup and should be specified under the [sst] group.

backup_threads

| Parameter | Description |
|-----------|-------------|
| Default: | 4 |

Specifies the number of threads that XtraBackup should use to create backups. See the --parallel option in XtraBackup.

This option affects only SST with XtraBackup and should be specified under the [sst] group.

9.2.2 XtraBackup SST dependencies

Each suppored version of Percona XtraDB Cluster is tested against a specific version of Percona XtraBackup:

- Percona XtraDB Cluster 5.6 requires Percona XtraBackup 2.3
- Percona XtraDB Cluster 5.7 requires Percona XtraBackup 2.4
- Percona XtraDB Cluster 8.0 requires Percona XtraBackup 8.0

Other combinations are not guaranteed to work.

The following are optional dependencies of Percona XtraDB Cluster introduced by wsrep_sst_xtrabackup-v2 (except for obvious and direct dependencies):

- qpress for decompression. It is an optional dependency of *Percona XtraBackup* and it is available in our software repositories.
- my_print_defaults to extract values from my.cnf. Provided by the server package.
- openbsd-netcat or socat for transfer. socat is a direct dependency of Percona XtraDB Cluster and it is the default.
- xbstream or tar for streaming. xbstream is the default.
- pv is required for progress and rlimit.
- mkfifo is required for progress. Provided by coreutils.
- mktemp is required. Provided by coreutils.
- which is required.

9.2.3 XtraBackup-based encryption

Settings related to XtraBackup-based Encryption are no longer allowed in PXC 8.0 when used for SST. If it is detected that XtraBackup-based Encryption is enabled, PXC will produce an error.

The XtraBackup-based Encryption is enabled when you specify any of the following options under [xtrabackup] in my.cnf:

- encrypt
- encrypt-key
- encrypt-key-file

9.2.4 Memory allocation

The amount of memory for XtraBackup is defined by the --use-memory option. You can pass it using the inno-apply-opts option under [sst] as follows:

```
[sst]
inno-apply-opts="--use-memory=500M"
```

If it is not specified, the use-memory option under [xtrabackup] will be used:

```
[xtrabackup]
use-memory=32M
```

If neither of the above are specified, the size of the InnoDB memory buffer will be used:

[mysqld] innodb buffer pool size=24M

Last update: 2023-07-21

9.3 Restart the cluster nodes

To restart a cluster node, shut down MySQL and restarting it. The node should leave the cluster (and the total vote count for quorum should decrement).

When it rejoins, the node should synchronize using IST. If the set of changes needed for IST are not found in the gcache file on any other node in the entire cluster, then SST will be performed instead. Therefore, restarting cluster nodes for rolling configuration changes or software upgrades is rather simple from the cluster's perspective.

If you restart a node with an invalid configuration change that prevents MySQL from loading, Galera will drop the node's state and force an SST for that node.

🖍 Note

If MySQL fails for any reason, it will not remove its PID file (which is by design deleted only on clean shutdown). Obviously server will not restart if existing PID file is present. So in case of encountered MySQL failure for any reason with the relevant records in log, PID file should be removed manually.

Last update: 2023-07-21

9.4 Cluster failover

Cluster membership is determined simply by which nodes are connected to the rest of the cluster; there is no configuration setting explicitly defining the list of all possible cluster nodes. Therefore, every time a node joins the cluster, the total size of the cluster is increased and when a node leaves (gracefully) the size is decreased.

The size of the cluster is used to determine the required votes to achieve quorum. A quorum vote is done when a node or nodes are suspected to no longer be part of the cluster (they do not respond). This no response timeout is the evs.suspect_timeout setting in the wsrep_provider_options (default 5 sec), and when a node goes down ungracefully, write operations will be blocked on the cluster for slightly longer than that timeout.

Once a node (or nodes) is determined to be disconnected, then the remaining nodes cast a quorum vote, and if the majority of nodes from before the disconnect are still still connected, then that partition remains up. In the case of a network partition, some nodes will be alive and active on each side of the network disconnect. In this case, only the quorum will continue. The partition(s) without quorum will change to non-primary state.

As a consequence, it's not possible to have safe automatic failover in a 2 node cluster, because failure of one node will cause the remaining node to become non-primary. Moreover, any cluster with an even number of nodes (say two nodes in two different switches) have some possibility of a *split brain* situation,

when neither partition is able to retain quorum if connection between them is lost, and so they both become non-primary.

Therefore, for automatic failover, the *rule of 3s* is recommended. It applies at various levels of your infrastructure, depending on how far the cluster is spread out to avoid single points of failure. For example:

- A cluster on a single switch should have 3 nodes
- A cluster spanning switches should be spread evenly across at least 3 switches
- A cluster spanning networks should span at least 3 networks
- A cluster spanning data centers should span at least 3 data centers

These rules will prevent split brain situations and ensure automatic failover works correctly.

9.4.1 Use an arbitrator

If it is too expensive to add a third node, switch, network, or datacenter, you should use an arbitrator. An arbitrator is a voting member of the cluster that can receive and relay replication, but it does not persist any data, and runs its own daemon instead of <code>mysqld</code>. Placing even a single arbitrator in a 3rd location can add split brain protection to a cluster that is spread across only two nodes/locations.

9.4.2 Recover a non-primary cluster

It is important to note that the *rule of 3s* applies only to automatic failover. In the event of a 2-node cluster (or in the event of some other outage that leaves a minority of nodes active), the failure of one node will cause the other to become non-primary and refuse operations. However, you can recover the node from non-primary state using the following command:

SET GLOBAL wsrep_provider_options='pc.bootstrap=true';

This will tell the node (and all nodes still connected to its partition) that it can become a primary cluster. However, this is only safe to do when you are sure there is no other partition operating in primary as well, or else Percona XtraDB Cluster will allow those two partitions to diverge (and you will end up with two databases that are impossible to re-merge automatically).

For example, assume there are two data centers, where one is primary and one is for disaster recovery, with an even number of nodes in each. When an extra arbitrator node is run only in the primary data center, the following high availability features will be available:

- Auto-failover of any single node or nodes within the primary or secondary data center
- Failure of the secondary data center would not cause the primary to go down (because of the arbitrator)
- Failure of the primary data center would leave the secondary in a non-primary state.
- If a disaster-recovery failover has been executed, you can tell the secondary data center to bootstrap itself with a single command, but disaster-recovery failover remains in your control.

9.4.3 Other reading

• PXC - Failure Scenarios with only 2 nodes

Last update: 2023-07-21

9.5 Monitor the cluster

Each node can have a different view of the cluster. There is no centralized node to monitor. To track down the source of issues, you have to monitor each node independently.

Values of many variables depend on the node from which you are querying. For example, replication sent from a node and writes received by all other nodes.

Having data from all nodes can help you understand where flow messages are coming from, which node sends excessively large transactions, and so on.

9.5.1 Manual monitoring

Manual cluster monitoring can be performed using myq-tools.

9.5.2 Alerting

Besides standard MySQL alerting, you should use at least the following triggers specific to Percona XtraDB Cluster:

Cluster state of each node

wsrep_cluster_status != Primary

Node state

wsrep_connected != ON

wsrep_ready != ON

For additional alerting, consider the following:

- Excessive replication conflicts can be identtified using the wsrep_local_cert_failures and wsrep_local_bf_aborts variables
- Excessive flow control messages can be identified using the wsrep_flow_control_sent and wsrep_flow_control_recv variables
- Large replication queues can be identified using the wsrep_local_recv_queue.

9.5.3 Metrics

Cluster metrics collection for long-term graphing should be done at least for the following:

• Queue sizes:

wsrep_local_recv_queue and wsrep_local_send_queue

• Flow control:

wsrep_flow_control_sent and wsrep_flow_control_recv

• Number of transactions for a node:

wsrep_replicated and wsrep_received

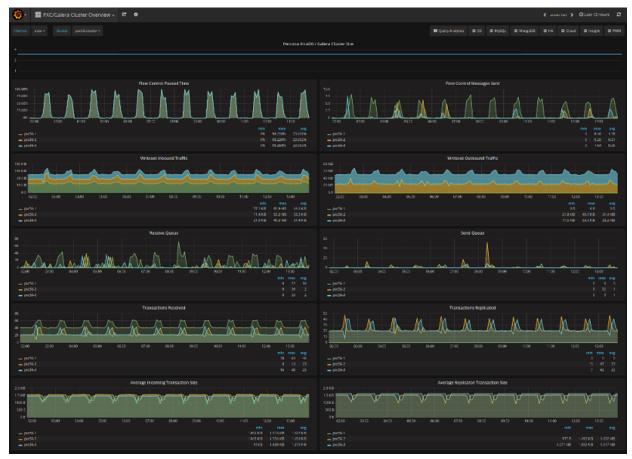

- Number of transactions in bytes:
- wsrep_replicated_bytes and wsrep_received_bytes
- Replication conflicts:

wsrep_local_cert_failures and wsrep_local_bf_aborts

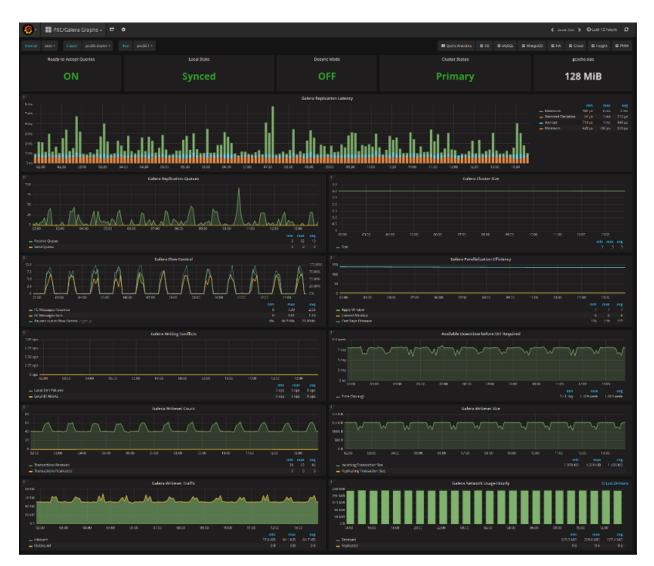

9.5.4 Use Percona Monitoring and Management

Percona Monitoring and Management includes two dashboards to monitor PXC:

1. PXC/Galera Cluster Overview:

2. PXC/Galera Graphs:

These dashboards are available from the menu:

| Query Analytics | ≡ os | ≡ MySQL | ≡ MongoDB | ≡ на | ≡ Cloud | ≡ Insight | ≡ РММ |
|-----------------|-------------|----------------|-----------|---------|----------------|-----------|-------|
| | | | | PXC/Gal | era Cluster O | verview | |
| | | | | PXC/Gal | era Graphs | | |
| | | | | ProxySC | L Overview | | |

Please refer to the official documentation for details on Percona Monitoring and Management installation and setup.

9.6 Certification in Percona XtraDB Cluster

Percona XtraDB Cluster replicates actions executed on one node to all other nodes in the cluster, and makes it fast enough to appear as if it is synchronous (*virtually synchronous*).

The following types of actions exist:

- DDL actions are executed using Total Order Isolation (TOI). We can ignore Rolling Schema Upgrades (ROI).
- DML actions are executed using normal Galera replication protocol.

🖍 Note

This manual page assumes the reader is aware of TOI and MySQL replication protocol.

DML (INSERT, UPDATE, and DELETE) operations effectively change the state of the database, and all such operations are recorded in XtraDB by registering a unique object identifier (key) for each change (an update or a new addition).

• A transaction can change an arbitrary number of different data objects. Each such object change is recorded in XtraDB using an append_key operation. An append_key operation registers the key of the data object that has undergone change by the transaction. The key for rows can be represented in three parts as db_name, table_name, and pk_columns_for_table (if pk is absent, a hash of the complete row is calculated).

This ensures that there is quick and short meta information about the rows that this transaction has touched or modified. This information is passed on as part of the write-set for certification to all the nodes in the cluster while the transaction is in the commit phase.

- For a transaction to commit, it has to pass XtraDB/Galera certification, ensuring that transactions don't conflict with any other changes posted on the cluster group/channel. Certification will add the keys modified by a given transaction to its own central certification vector (CCV), represented by cert_index_ng. If the said key is already part of the vector, then conflict resolution checks are triggered.
- Conflict resolution traces the reference transaction (that last modified this item in the cluster group). If this reference transaction is from some other node, that suggests the same data was modified by the other node, and changes of that node have been certified by the local node that is executing the check. In such cases, the transaction that arrived later fails to certify.

Changes made to database objects are bin-logged. This is similar to how MySQL does it for replication with its Source-Replica ecosystem, except that a packet of changes from a given transaction is created and named as a write-set.

Once the client/user issues a COMMIT, Percona XtraDB Cluster will run a commit hook. Commit hooks ensure the following:

- Flush the binary logs.
- Check if the transaction needs replication (not needed for read-only transactions like SELECT).
- If a transaction needs replication, then it invokes a pre-commit hook in the Galera ecosystem. During this pre-commit hook, a write-set is written in the group channel by a *replicate* operation. All nodes (including the one that executed the transaction) subscribe to this group-channel and read the write-set.
- gcs_recv_thread is the first to receive the packet, which is then processed through different action handlers.
- Each packet read from the group-channel is assigned an id, which is a locally maintained counter by each node in sync with the group. When any new node joins the group/cluster, a seed-id for it is initialized to the current active id from group/cluster.

There is an inherent assumption/protocol enforcement that all nodes read the packet from a channel in the same order, and that way even though each packet doesn't carry id information, it is inherently established using the locally maintained id value.

9.6.1 Common situation

The following example shows what happens in a common situation. act_id is incremented and assigned only for totally ordered actions, and only in primary state (skip messages while in state exchange).

rcvd->id = ++group->act_id_;

🖍 Note

This is an amazing way to solve the problem of the id coordination in multi-source systems. Otherwise a node will have to first get an id from central system or through a separate agreed protocol, and then use it for the packet, thereby doubling the round-trip time.

9.6.2 Conflicts

The following happens if two nodes get ready with their packet at same time:

- 1. Both nodes will be allowed to put the packet on the channel. That means the channel will see packets from different nodes queued one behind another.
- 2. The following example shows what happens if two nodes modify same set of rows. Nodes are in sync until this point:

```
create -> insert (1,2,3,4)
```

- Node 1: update i = i + 10;
- Node 2: update i = i + 100;

Let's associate transaction ID (trx-id) for an update transaction that is executed on Node 1 and Node 2 in parallel. Although the real algorithm is more involved (with uuid + seqno), it is conceptually the same, so we are using trx_id .

- Node l: update action: trx-id=nlx
- Node 2: update action: trx-id=n2x

Both node packets are added to the channel, but the transactions are conflicting. The protocol says: FIRST WRITE WINS.

So in this case, whoever is first to write to the channel will get certified. Let's say Node 2 is first to write the packet, and then Node 1 makes changes immediately after it.

Each node subscribes to all packages, including its own package.

- Node 2 will see its own packet and will process it. Then it will see the packet from Node 1, try to certify it, and fail.
- Node 1 will see the packet from Node 2 and will process it.

InnoDB allows isolation, so Node 1 can process packets from Node 2 independent of Node 1 transaction changes

Then Node 1 will see its own packet, try to certify it, and fail.

🖍 Note

Even though the packet originated from Node 1, it will undergo certification to catch cases like these.

9.6.3 Resolve certification conflicts

The certification protocol can be described using the previous example. The central certification vector (CCV) is updated to reflect reference transaction.

• Node 2 sees its own packet for certification, adds it to its local CCV and performs certification checks. Once these checks pass, it updates the reference transaction by setting it to in2x.

Node 2 then gets the packet from Node 1 for certification. The packet key is already present in CCV, with the reference transaction set it to n2x, whereas write-set proposes setting it to n1x. This causes a conflict, which in turn causes the transaction from Node 1 to fail the certification test.

• Node 1 sees the packet from Node 2 for certification, which is then processed, the local CCV is updated, and the reference transaction is set to in2x.

Using the same case as explained above, Node 1 certification also rejects the packet from Node 1.

This suggests that the node doesn't need to wait for certification to complete, but just needs to ensure that the packet is written to the channel. The applier transaction will always win and the local conflicting transaction will be rolled back.

The following example shows what happens if one of the nodes has local changes that are not synced with the group:

create (id primary key) -> insert (1), (2), (3), (4);

Expected output

```
node-1: wsrep_on=0; insert (5); wsrep_on=1
node-2: insert(5).
```

The insert(5) statement will generate a write-set that will then be replicated to Node 1. Node 1 will try to apply it but will fail with duplicate-key-error, because 5 already exist.

XtraDB will flag this as an error, which would eventually cause Node 1 to shutdown.

9.6.4 Increment GTID

GTID is incremented only when the transaction passes certification, and is ready for commit. That way errant packets don't cause GTID to increment.

Also, group packet id is not confused with GTID. Without errant packets, it may seem that these two counters are the same, but they are not related.

9.7 Percona XtraDB Cluster threading model

Percona XtraDB Cluster creates a set of threads to service its operations, which are not related to existing MySQL threads. There are three main groups of threads:

9.7.1 Applier threads

Applier threads apply write-sets that the node receives from other nodes. Write messages are directed through gcv_recv_thread.

The number of applier threads is controlled using the wsrep_slave_threads variable or the wsrep_applier_threads variable. The wsrep_slave_threads variable was deprecated in the Percona XtraDB Cluster 8.0.26-16 release. The default value is 1, which means at least one wsrep applier thread exists to process the request.

Applier threads wait for an event, and once it gets the event, it applies it using normal replica apply routine path, and relays the log info apply path with wsrep-customization. These threads are similar to replica worker threads (but not exactly the same).

Coordination is achieved using *Apply and Commit Monitor*. A transaction passes through two important states: APPLY and COMMIT. Every transaction registers itself with an apply monitor, where its apply order is defined. So all transactions with apply order sequence number (seqno) of less than this transaction's sequence number, are applied before applying this transaction. The same is done for commit as well (last_left >= trx_.depends_seqno()).

9.7.2 Rollback thread

There is only one rollback thread to perform rollbacks in case of conflicts.

- Transactions executed in parallel can conflict and may need to roll back.
- Applier transactions always take priority over local transactions. This is natural, as applier transactions have been accepted by the cluster, and some of the nodes may have already applied them. Local conflicting transactions still have a window to rollback.

All the transactions that need to be rolled back are added to the rollback queue, and the rollback thread is notified. The rollback thread then iterates over the queue and performs rollback operations.

If a transaction is active on a node, and a node receives a transaction write-set from the cluster group that conflicts with the local active transaction, then such local transactions are always treated as a victim transaction to roll back.

Transactions can be in a commit state or an execution stage when the conflict arises. Local transactions in the execution stage are forcibly killed so that the waiting applier transaction is allowed to proceed. Local transactions in the commit stage fail with a certification error.

9.7.3 Other threads

Service thread

This thread is created during boot-up and used to perform auxiliary services. It has two main functions:

- It releases the GCache buffer after the cached write-set is purged up to the said level.
- It notifies the cluster group that the respective node has committed a transaction up to this level. Each node maintains some basic status info about other nodes in the cluster. On receiving the message, the information is updated in this local metadata.

Receiving thread

The gcs_recv_thread thread is the first one to see all the messages received in a group.

It will try to assign actions against each message it receives. It adds these messages to a central FIFO queue, which are then processed by the Applier threads. Messages can include different operations like state change, configuration update, flow-control, and so on.

One important action is processing a write-set, which actually is applying transactions to database objects.

Gcomm connection thread

The gcomm connection thread GCommConn::run_fn is used to co-ordinate the low-level group communication activity. Think of it as a black box meant for communication.

Action-based threads

Besides the above, some threads are created on a needed basis. SST creates threads for donor and joiner (which eventually forks out a child process to host the needed SST script), IST creates receiver and async sender threads, PageStore creates a background thread for removing the files that were created.

If the checksum is enabled and the replicated write-set is big enough, the checksum is done as part of a separate thread.

9.8 Understand GCache and Record-Set cache

In Percona XtraDB Cluster, there is a concept of GCache and Record-Set cache (which can also be called transaction write-set cache). The use of these two caches is often confusing if you are running long transactions, because both of them result in the creation of disk-level files. This manual describes what their main differences are.

9.8.1 Record-Set cache

When you run a long-running transaction on any particular node, it will try to append a key for each row that it tries to modify (the key is a unique identifier for the row {db,table,pk.columns}). This information is cached in out-write-set, which is then sent to the group for certification.

Keys are cached in HeapStore (which has page-size=64K and total-size=4MB). If the transaction data-size outgrows this limit, then the storage is switched from Heap to Page (which has page-size=64MB and total-limit=free-space-on-disk).

All these limits are non-configurable, but having a memory-page size greater than 4MB per transaction can cause things to stall due to memory pressure, so this limit is reasonable. This is another limitation to address when Galera supports large transaction.

The same long-running transaction will also generate binlog data that also appends to out-write-set on commit (HeapStore->FileStore). This data can be significant, as it is a binlog image of rows inserted/ updated/deleted by the transaction. The wsrep_max_ws_size variable controls the size of this part of the write-set. The threshold doesn't consider size allocated for caching-keys and the header.

If FileStore is used, it creates a file on the disk (with names like xxxx_keys and xxxx_data) to store the cache data. These files are kept until a transaction is committed, so the lifetime of the transaction is linked.

When the node is done with the transaction and is about to commit, it will generate the final-write-set using the two files (if the data size grew enough to use FileStore) plus HEADER, and will publish it for certification to cluster.

The native node executing the transaction will also act as subscription node, and will receive its own writeset through the cluster publish mechanism. This time, the native node will try to cache write-set into its GCache. How much data GCache retains is controlled by the GCache configuration.

9.8.2 GCache

GCache holds the write-set published on the cluster for replication. The lifetime of write-set in GCache is not transaction-linked.

When a JOINER node needs an IST, it will be serviced through this GCache (if possible).

GCache will also create the files to disk. You can read more about it here.

At any given point in time, the native node has two copies of the write-set: one in GCache and another in Record-Set Cache.

For example, lets say you INSERT/UPDATE 2 million rows in a table with the following schema.

(int, char(100), char(100) with pk (int, char(100))

It will create write-set key/data files in the background similar to the following:

-rw----- 1 xxx xxx 67108864 Apr 11 12:26 0x0000707_data.000000 -rw----- 1 xxx xxx 67108864 Apr 11 12:26 0x00000707_data.000001 -rw----- 1 xxx xxx 67108864 Apr 11 12:26 0x00000707_data.000002 -rw----- 1 xxx xxx 67108864 Apr 11 12:26 0x00000707_keys.000000

9.9 GCache encryption and Write-Set cache encryption

These features are tech preview. Before using these features in production, we recommend that you test restoring production from physical backups in your environment, and also use the alternative backup method for redundancy.

9.9.1 GCache and Write-Set cache encryption

Enabling this feature encrypts the Galera GCache and Write-Set cache files with a File Key.

GCache has a RingBuffer on-disk file to manage write-sets. The keyring only stores the Master Key which is used to encrypt the File Key used by the RingBuffer file. The encrypted File Key is stored in the RingBuffer's preamble. The RingBuffer file of GCache is non-volatile, which means this file survives a restart. The File Key is not stored for GCache off-pages and Write-Set cache files.

For more information, see Understanding GCache and Record-set Cache, and the Percona Database Performance Blog: All you need to know about GCache

Sample preamble key-value pairs

```
Version: 2
GID: 3afaa7ld-6665-11ed-98de-2aba4aabc65e
synced: 0
enc_version: 1
enc_encrypted: 1
enc_mk_id: 3
enc_mk_const_id: 3ad045a2-6665-11ed-a49d-cb7b9d88753f
enc_mk_uuid: 3ad04c8e-6665-11ed-a947-c7e346da147f
enc_fk_id: S4hRiibUje4v5GSQ7a+uuS6NBBX9+230nsPHeAXH43k=
enc_crc: 279433530
```

Description

Key descriptions

Kov

The following table describes the encryption keys defined in the preamble. All other keys in the preamble are not related to encryption.

| Rey | Description | |
|---------------|--|--|
| enc_version | The encryption version | |
| enc_encrypted | If the GCache is encrypted or not | |
| enc_mk_id | A part of the Master Key ID. Rotating the Master Key increments the sequence number. | |

| Кеу | Description |
|-----------------|---|
| enc_mk_const_id | A part of the Master Key ID, a constant Universally unique identifier (UUID). This option remains constant for the duration of the galera.gcache file and simplifies matching the Masater Key inside the keyring to the instance that generated the keys. Deleting the galera.gcache changes the value of this key. |
| enc_mk_uuid | The first Master Key or if Galera detects that the preamble is inconsistent, which causes a full GCache reset and a new Master Key is required, generates this UUID. |
| enc_fk_id | The File Key ID encrypted with the Master Key. |
| enc_crc | The cyclic redundancy check (CRC) calculated from all encryption-related keys. |

Controlling encryption

Encryption is controlled using the wsrep_provider_options.

| Variable name | Default value | Allowed values |
|--|---------------|----------------|
| gcache.encryption | off | on/off |
| <pre>gcache.encryption_cache_page_size</pre> | 32КВ | 2-512 |
| gcache.encryption_cache_size | 16MB | 2 - 512 |
| allocator.disk_pages_encryption | off | on/off |
| allocator.encryption_cache_page_size | 32КВ | |
| allocator.encryption_cache_size | 16MB | |

9.9.2 Rotate the GCache Master Key

GCache and Write-Set cache encryption uses either a keyring plugin or a keyring component. This plugin or component must be loaded.

Store the keyring file outside the data directory when using a keyring plugin or a keyring component.

mysql> ALTER INSTANCE ROTATE GCACHE MASTER KEY;

9.9.3 Variable descriptions

GCache encryption

The following sections describe the variables related to GCache encryption. All variables are read-only.

GCACHE.ENCRYPTION

Enable or disable GCache cache encryption.

GCACHE.ENCRYPTION_CACHE_PAGE_SIZE

The size of the GCache encryption page. The value must be multiple of the CPU page size (typically 4kB). If the value is not, the server reports an error and stops.

GCACHE.ENCRYPTION_CACHE_SIZE

Every encrypted file has an encryption.cache, which consists of pages. Use gcache.encryption_cache_size to configure the encryption.cache size.

Configure the page size in the cache with gcache.encryption_cache_page_size.

The maximum size for the encryption.cache is 512 pages. This value is a hint. If the value is larger than the maximum, the value is rounded down to 512 x gcache.encryption_cache_page_size.

The minimum size for the encryption.cache is 2 pages. If the value is smaller, the value is rounded up.

Write-Set cache encryption

The following sections describe the variables related to Write-Set cache encryption. All variables are readonly.

ALLOCATOR.DISK_PAGES_ENCRYPTION

Enable or disable the Write-Set cache encryption.

ALLOCATOR.ENCRYPTION_CACHE_PAGE_SIZE

The size of the encryption cache for Write-Set pages. The value must be multiple of the CPU page size (typically 4kB). If the value is not, the server reports an error and stops.

ALLOCATOR.ENCRYPTION_CACHE_SIZE

Every Write-Set encrypted file has an encryption.cache, which consists of pages. Use allocator.encryption_cache_size to configure the size of the encryption.cache.

Configure the page size in the cache with allocator.encryption_cache_page_size.

The maximum size for the encryption.cache is 512 pages. This value is a hint. If the value is larger than the maximum, the value is rounded down to 512 x gcache.encryption_cache_page_size.

The minimum size for the encryption.cache is 2 pages. If the value is smaller, the value is rounded up.

Last update: 2023-07-21

9.10 Perfomance Schema instrumentation

To improve monitoring *Percona XtraDB Cluster* has implemented an infrastructure to expose Galera instruments (mutexes, cond-variables, files, threads) as a part of PERFORMANCE_SCHEMA.

Although mutexes and condition variables from wsrep were already part of PERFORMANCE_SCHEMA threads were not.

Mutexes, condition variables, threads, and files from Galera library also were not part of the PERFORMANCE SCHEMA.

You can see the complete list of available instruments by running:

mysql> SELECT * FROM performance_schema.setup_instruments WHERE name LIKE '%galera%' OR
name LIKE '%wsrep%';

| Expected output | |
|---|-----------------|
| | |
| + | + |
| NAME | ENABLED TIMED |
| + | + |
| <pre>wait/synch/mutex/sql/LOCK_wsrep_ready</pre> | NO NO |
| wait/synch/mutex/sql/LOCK wsrep sst | NO NO |
| <pre>wait/synch/mutex/sql/LOCK_wsrep_sst_init</pre> | NO NO |
| | |
| <pre>stage/wsrep/wsrep: in rollback thread</pre> | NO NO |
| stage/wsrep/wsrep: aborter idle | I NO I NO I |
| stage/wsrep/wsrep: aborter active | NO NO NO |
| + | + |
| 73 rows in set (0.00 sec) | |
| | |

Some of the most important are:

- Two main actions that Galera does are REPLICATION and ROLLBACK. Mutexes, condition variables, and threads related to this are part of PERFORMANCE_SCHEMA.
- Galera internally uses monitor mechanism to enforce ordering of events. These monitor control events apply and are mainly responsible for the wait between different action. All such monitor mutexes and condition variables are covered as part of this implementation.
- There are lot of other miscellaneous action related to receiving of package and servicing messages. Mutexes and condition variables needed for them are now visible too. Threads that manage receiving and servicing are also being instrumented.

This feature has exposed all the important mutexes, condition variables that lead to lock/threads/files as part of this process.

Besides exposing file it also tracks write/read bytes like stats for file. These stats are not exposed for Galera files as Galera uses immap.

Also, there are some threads that are short-lived and created only when needed especially for SST/IST purpose. They are also tracked but come into PERFORMANCE_SCHEMA tables only if/when they are created.

Stage Info from Galera specific function which server updates to track state of running thread is also visible in PERFORMANCE_SCHEMA.

9.10.1 What is not exposed ?

Galera uses customer data-structure in some cases (like STL structures). Mutexes used for protecting these structures which are not part of mainline Galera logic or doesn't fall in big-picture are not tracked. Same goes with threads that are gcomm library specific.

Galera maintains a process vector inside each monitor for its internal graph creation. This process vector is 65K in size and there are two such vectors per monitor. That is 128K * 3 = 384K condition variables. These are not tracked to avoid hogging PERFORMANCE_SCHEMA limits and sidelining of the main crucial information.

9.10.2 Use pxc_cluster_view

The pxc_cluster_view - provides a unified view of the cluster. The table is in the Performance_Schema database.

DESCRIBE pxc cluster view;

This table has the following definition:

To view the table, run the following query:

```
SELECT * FROM pxc cluster view;
```

```

9.11 Data at Rest Encryption

9.11.1 Introduction

The *data at rest* encryption refers to encrypting data stored on a disk on a server. If an unauthorized user accesses the data files from the file system, encryption ensures the user cannot read the file contents. Percona Server allows you to enable, disable, and apply encryptions to the following objects:

- File-per-tablespace table
- Schema
- General tablespace
- System tablespace
- Temporary table
- Binary log files
- Redo log files
- Undo tablespaces
- Doublewrite buffer files

The transit data is defined as data that is transmitted to another node or client. Encrypted transit data uses an SSL connection.

Percona XtraDB Cluster 8.0 supports all *data at rest* generally-available encryption features available from Percona Server for MySQL 8.0.

9.11.2 Configure PXC to use keyring_file plugin

Configuration

Percona XtraDB Cluster inherits the Percona Server for MySQL behavior to configure the keyring_file plugin. Install the plugin and add the following options in the configuration file:

```
[mysqld]
early-plugin-load=keyring_file.so
keyring file data=<PATH>/keyring
```

The SHOW PLUGINS statement checks if the plugin has been successfully loaded.

PXC recommends the same configuration on all cluster nodes, and all nodes should have the keyring configured. A mismatch in the keyring configuration does not allow the JOINER node to join the cluster.

If the user has a bootstrapped node with keyring enabled, then upcoming cluster nodes inherit the keyring (the encrypted key) from the DONOR node.

USAGE

XtraBackup re-encrypts the data using a transition-key and the JOINER node re-encrypts it using a newly generated master-key.

Keyring (or, more generally, the Percona XtraDB Cluster SST process) is backward compatible, as in higher version JOINER can join from lower version DONOR, but not vice-versa.

Percona XtraDB Cluster does not allow the combination of nodes with encryption and nodes without encryption to maintain data consistency. For example, the user creates node-1 with encryption (keyring) enabled and node-2 with encryption (keyring) disabled. If the user attempts to create a table with encryption on node-1, the creation fails on node-2, causing data inconsistency. A node fails to start if it fails to load the keyring plugin.

If the user does not specify the keyring parameters, the node does not know that it must load the keyring. The JOINER node may start, but it eventually shuts down when the DML level inconsistency with encrypted tablespace is detected.

If a node does not have an encrypted tablespace, the keyring is not generated, and the keyring file is empty. Creating an encrypted table on the node generates the keyring.

In an operation that is local to the node, you can rotate the key as needed. The ALTER INSTANCE ROTATE INNODE MASTER KEY statement is not replicated on cluster.

The JOINER node generates its keyring.

Compatibility

Keyring (or, more generally, the Percona XtraDB Cluster SST process) is backward compatible. A higher version JOINER can join from lower version DONOR, but not vice-versa.

9.11.3 Configure PXC to use keyring_vault plugin

keyring_vault

The keyring_vault plugin allows storing the master-key in vault-server (vs. local file as in case of keyring_file).

🛕 Warning

The rsync tool does not support the keyring_vault. Any rysnc-SST on a joiner is aborted if the keyring_vault is configured.

Configuration

Configuration options are the same as upstream. The my.cnf configuration file should contain the following options:

```
[mysqld]
early-plugin-load="keyring_vault=keyring_vault.so"
keyring_vault_config="<PATH>/keyring_vault_n1.conf"
```

Also, keyring_vault_n1.conf file should contain the following:

```
vault_url = http://127.0.0.1:8200
secret_mount_point = secret1
token = e0345eb4-35dd-3b1e-e42bb9f2525d
vault_ca = /data/keyring_vault_confs/vault_ca.crt
```

The detailed description of these options can be found in the upstream documentation.

Vault-server is an external server, so make sure the PXC node can reach the server.

Percona XtraDB Cluster recommends using the same keyring_plugin type on all cluster nodes. Mixing the keyring plugin types is recommended only while transitioning from keyring_file -> keyring_vault or vice-versa.

All nodes do not need to refer to the same vault server. Whatever vault server is used, it must be accessible from the respective node. All nodes do not need to use the same mount point.

If the node is not able to reach or connect to the vault server, an error is notified during the server boot, and the node refuses to start:

The warning message 2018-05-29T03:54:33.859613Z 0 [Warning] Plugin keyring_vault reported: 'There is no vault_ca specified in keyring_vault's configuration file. Please make sure that Vault's CA certificate is trusted by the machine from which you intend to connect to Vault.' 2018-05-29T03:54:33.977145Z 0 [ERROR] Plugin keyring_vault reported: 'CURL returned this error code: 7 with error message : Failed to connect to 127.0.0.1 port 8200: Connection refused'

If some nodes of the cluster are unable to connect to vault-server, this relates only to these specific nodes: e.g., if node-1 can connect, and node-2 cannot connect, only node-2 refuses to start. Also, if the server has a pre-existing encrypted object and on reboot, the server fails to connect to the vault-server, the object is not accessible.

In case when vault-server is accessible, but authentication credential is incorrect, the consequences are the same, and the corresponding error looks like the following:

The warning message

```
2018-05-29T03:58:54.461911Z 0 [Warning] Plugin keyring_vault reported:

'There is no vault_ca specified in keyring_vault's configuration file.

Please make sure that Vault's CA certificate is trusted by the machine

from which you intend to connect to Vault.'

2018-05-29T03:58:54.577477Z 0 [ERROR] Plugin keyring_vault reported:

'Could not retrieve list of keys from Vault. Vault has returned the

following error(s): ["permission denied"]'
```

In case of an accessible vault-server with the wrong mount point, there is no error during server boot, but the node still refuses to start:

mysql> CREATE TABLE t1 (c1 INT, PRIMARY KEY pk(c1)) ENCRYPTION='Y';

Expected output

```
ERROR 3185 (HY000): Can't find master key from keyring, please check keyring plugin is loaded.
```

... [ERROR] Plugin keyring_vault reported: 'Could not write key to Vault. [ERROR] Plugin keyring_vault reported: 'Could not flush keys to keyring'

9.11.4 Mix keyring plugin types

With XtraBackup introducing transition-key logic, it is now possible to mix and match keyring plugins. For example, the user has node-1 configured to use the keyring_file plugin and node-2 configured to use keyring_vault.

Percona recommends the same configuration for all the nodes of the cluster. A mix and match in keyring plugin types is recommended only during the transition from one keying type to another.

9.11.5 Temporary file encryption

9.11.6 Migrate keys between keyring keystores

Percona XtraDB Cluster supports key migration between keystores. The migration can be performed offline or online.

Offline migration

In offline migration, the node to migrate is shut down, and the migration server takes care of migrating keys for the said server to a new keystore.

For example, a cluster has three Percona XtraDB Cluster nodes, n1, n2, and n3. The nodes use the keyring_file. To migrate the n2 node to use keyring_vault, use the following procedure:

- 1. Shut down the n2 node.
- 2. Start the Migration Server (mysqld with a special option).
- 3. The Migration Server copies the keys from the n2 keyring file and adds them to the vault server.
- 4. Start the n2 node with the vault parameter, and the keys are available.

Here is how the migration server output should look like:

| Expected output | |
|---|--|
| <pre>/dev/shm/pxc80/bin/mysqlddefaults-file=/dev/shm/pxc80/copy_mig.cnf \ keyring-migration-source=keyring_file.so \ keyring_file_data=/dev/shm/pxc80/node2/keyring \ keyring-migration-destination=keyring_vault.so \ keyring_vault_config=/dev/shm/pxc80/vault/keyring_vault.cnf & [Warning] TIMESTAMP with implicit DEFAULT value is deprecated. Please use explicit_defaults_for_timestamp server option (see documentation for more details). [Note]secure-file-priv is set to NULL. Operations related to importing and exporting data are disabled [Warning] WSREP: Node is not a cluster node. Disabling pxc_strict_mode [Note] /dev/shm/pxc80/bin/mysqld (mysqld 8.0-debug) starting as process 5710 [Note] Keyring migration successful.</pre> | |

On a successful migration, the destination keystore receives additional migrated keys (pre-existing keys in the destination keystore are not touched or removed). The source keystore retains the keys as the migration performs a copy operation and not a move operation.

If the migration fails, the destination keystore is unchanged.

Online migration

In online migration, the node to migrate is kept running, and the migration server takes care of migrating keys for the said server to a new keystore by connecting to the node.

For example, a cluster has three Percona XtraDB Cluster nodes, n1, n2, and n3. The nodes use the keyring_file. Migrate the n3 node to use keyring_vault using the following procedure:

- 1. Start the Migration Server (mysqld with a special option).
- 2. The Migration Server copies the keys from the n3 keyring file and adds them to the vault server.

3. Restart the n3 node with the vault parameter, and the keys are available.

```
/dev/shm/pxc80/bin/mysqld --defaults-file=/dev/shm/pxc80/copy mig.cnf \
```

- --keyring-migration-source=keyring_vault.so \
- --keyring_vault_config=/dev/shm/pxc80/keyring_vault3.cnf \
- --keyring-migration-destination=keyring_file.so \
- --keyring_file_data=/dev/shm/pxc80/node3/keyring \
- --keyring-migration-host=localhost $\$
- --keyring-migration-user=root $\$
- --keyring-migration-port=16300 $\$
- --keyring-migration-password='' &

On a successful migration, the destination keystore receives the additional migrated keys. Any pre-existing keys in the destination keystore are unchanged. The source keystore retains the keys as the migration performs a copy operation and not a move operation.

If the migration fails, the destination keystore is not changed.

Migration server options

- -- keyring-migration-source : The source keyring plugin that manages the keys to be migrated.
- --keyring-migration-destination: The destination keyring plugin to which the migrated keys are to be copied

🖍 Note

For offline migration, no additional key migration options are needed.

- --keyring-migration-host : The host where the running server is located. This host is always the local host.
- -- keyring-migration-user, -- keyring-migration-password: The username and password for the account used to connect to the running server.
- -- keyring-migration-port : Used for TCP/IP connections, the running server's port number used to connect.
- --keyring-migration-socket: Used for Unix socket file or Windows named pipe connections, the running server socket or named pipe used to connect.

Prerequisite for migration:

Make sure to pass required keyring options and other configuration parameters for the two keyring plugins. For example, if keyring_file is one of the plugins, you must explicitly configure the keyring_file_data system variable in the my.cnf file.

Other non-keyring options may be required as well. One way to specify these options is by using --defaults-file to name an option file that contains the required options.

```
[mysqld]
basedir=/dev/shm/pxc80
datadir=/dev/shm/pxc80/copy_mig
log-error=/dev/shm/pxc80/logs/copy_mig.err
socket=/tmp/copy_mig.sock
port=16400
```

Last update: 2023-07-21

10. How-tos

10.1 Crash recovery

Unlike the standard MySQL replication, a PXC cluster acts like one logical entity, which controls the status and consistency of each node as well as the status of the whole cluster. This allows maintaining the data integrity more efficiently than with traditional asynchronous replication without losing safe writes on multiple nodes at the same time.

However, there are scenarios where the database service can stop with no node being able to serve requests.

10.1.1 Scenario 1: Node A is gracefully stopped

In a three node cluster (node A, Node B, node C), one node (node A, for example) is gracefully stopped: for the purpose of maintenance, configuration change, etc.

In this case, the other nodes receive a "good bye" message from the stopped node and the cluster size is reduced; some properties like quorum calculation or auto increment are automatically changed. As soon as node A is started again, it joins the cluster based on its wsrep_cluster_address variable in my.cnf.

If the writeset cache (gcache.size) on nodes B and/or C still has all the transactions executed while node A was down, joining is possible via IST. If IST is impossible due to missing transactions in donor's gcache, the fallback decision is made by the donor and SST is started automatically.

10.1.2 Scenario 2: Two nodes are gracefully stopped

Similar to Scenario 1: Node A is gracefully stopped, the cluster size is reduced to 1 - even the single remaining node C forms the primary component and is able to serve client requests. To get the nodes back into the cluster, you just need to start them.

However, when a new node joins the cluster, node C will be switched to the "Donor/Desynced" state as it has to provide the state transfer at least to the first joining node. It is still possible to read/write to it during that process, but it may be much slower, which depends on how large amount of data should be sent during the state transfer. Also, some load balancers may consider the donor node as not operational and remove it from the pool. So, it is best to avoid the situation when only one node is up.

If you restart node A and then node B, you may want to make sure note B does not use node A as the state transfer donor: node A may not have all the needed writesets in its gcache. Specify node C node as the donor in your configuration file and start the mysql service:

\$ systemctl start mysql

10.1.3 Scenario 3: All three nodes are gracefully stopped

The cluster is completely stopped and the problem is to initialize it again. It is important that a PXC node writes its last executed position to the grastate.dat file.

By comparing the seqno number in this file, you can see which is the most advanced node (most likely the last stopped). The cluster must be bootstrapped using this node, otherwise nodes that had a more advanced position will have to perform the full SST to join the cluster initialized from the less advanced one. As a result, some transactions will be lost). To bootstrap the first node, invoke the startup script like this:

\$ systemctl start mysql@bootstrap.service

Even though you bootstrap from the most advanced node, the other nodes have a lower sequence number. They will still have to join via the full SST because the *Galera Cache* is not retained on restart.

For this reason, it is recommended to stop writes to the cluster *before* its full shutdown, so that all nodes can stop at the same position. See also pc.recovery.

10.1.4 Scenario 4: One node disappears from the cluster

This is the case when one node becomes unavailable due to power outage, hardware failure, kernel panic, mysqld crash, **kill -9** on mysqld pid, etc.

Two remaining nodes notice the connection to node A is down and start trying to re-connect to it. After several timeouts, node A is removed from the cluster. The quorum is saved (2 out of 3 nodes are up), so no service disruption happens. After it is restarted, node A joins automatically (as described in Scenario 1: Node A is gracefully stopped).

10.1.5 Scenario 5: Two nodes disappear from the cluster

Two nodes are not available and the remaining node (node C) is not able to form the quorum alone. The cluster has to switch to a non-primary mode, where MySQL refuses to serve any SQL queries. In this state, the **mysqld** process on node C is still running and can be connected to but any statement related to data fails with an error

> SELECT * FROM test.sbtest1;

The error message

ERROR 1047 (08S01): WSREP has not yet prepared node for application use

Reads are possible until node C decides that it cannot access node A and node B. New writes are forbidden.

As soon as the other nodes become available, the cluster is formed again automatically. If node B and node C were just network-severed from node A, but they can still reach each other, they will keep functioning as they still form the quorum.

If node A and node B crashed, you need to enable the primary component on node C manually, before you can bring up node A and node B. The command to do this is:

> SET GLOBAL wsrep provider options='pc.bootstrap=true';

This approach only works if the other nodes are down before doing that! Otherwise, you end up with two clusters having different data.

| 🖍 See also | |
|-------------------------|--|
| Adding Nodes to Cluster | |

10.1.6 Scenario 6: All nodes went down without a proper shutdown procedure

This scenario is possible in case of a datacenter power failure or when hitting a MySQL or Galera bug. Also, it may happen as a result of data consistency being compromised where the cluster detects that each node has different data. The grastate.dat file is not updated and does not contain a valid sequence number (seqno). It may look like this:

```
$ cat /var/lib/mysql/grastate.dat
# GALERA saved state
version: 2.1
uuid: 220dcdcb-1629-11e4-add3-aec059ad3734
seqno: -1
safe_to_bootstrap: 0
```

In this case, you cannot be sure that all nodes are consistent with each other. We cannot use safe_to_bootstrap variable to determine the node that has the last transaction committed as it is set to **0** for each node. An attempt to bootstrap from such a node will fail unless you start mysqld with the --wsrep-recover parameter:

```
$ mysqld --wsrep-recover
```

Search the output for the line that reports the recovered position after the node UUID (1122 in this case):

```
Expected output

...
...
[Note] WSREP: Recovered position: 220dcdcb-1629-11e4-add3-aec059ad3734:1122
...
```

The node where the recovered position is marked by the greatest number is the best bootstrap candidate. In its grastate.dat file, set the safe_to_bootstrap variable to **1**. Then, bootstrap from this node.

🖍 Note

After a shutdown, you can boostrap from the node which is marked as safe in the grastate.dat file.

```
...
safe_to_bootstrap: 1
...
```

Galera Documentation Introducing the Safe-To-Bootstrap feature in Galera Cluster

In recent Galera versions, the option pc.recovery (enabled by default) saves the cluster state into a file named gvwstate.dat on each member node. As the name of this option suggests (pc – primary component), it saves only a cluster being in the PRIMARY state. An example content of the file may look like this:

cat /var/lib/mysql/gvwstate.dat my_uuid: 76de8ad9-2aac-11e4-8089-d27fd06893b9 #vwbeg view_id: 3 6c821ecc-2aac-11e4-85a5-56fe513c651f 3 bootstrap: 0 member: 6c821ecc-2aac-11e4-85a5-56fe513c651f 0 member: 6d80ec1b-2aac-11e4-8d1e-b2b2f6caf018 0 member: 76de8ad9-2aac-11e4-8089-d27fd06893b9 0 #vwend

We can see a three node cluster with all members being up. Thanks to this new feature, the nodes will try to restore the primary component once all the members start to see each other. This makes the PXC cluster automatically recover from being powered down without any manual intervention! In the logs we will see:

10.1.7 Scenario 7: The cluster loses its primary state due to split brain

For the purpose of this example, let's assume we have a cluster that consists of an even number of nodes: six, for example. Three of them are in one location while the other three are in another location and they lose network connectivity. It is best practice to avoid such topology: if you cannot have an odd number of real nodes, you can use an additional arbitrator (garbd) node or set a higher pc.weight to some nodes. But when the split brain happens any way, none of the separated groups can maintain the quorum: all nodes must stop serving requests and both parts of the cluster will be continuously trying to re-connect.

If you want to restore the service even before the network link is restored, you can make one of the groups primary again using the same command as described in Scenario 5: Two nodes disappear from the cluster

> SET GLOBAL wsrep_provider_options='pc.bootstrap=true';

After this, you are able to work on the manually restored part of the cluster, and the other half should be able to automatically re-join using IST as soon as the network link is restored.

👠 Warning

If you set the bootstrap option on both the separated parts, you will end up with two living cluster instances, with data likely diverging away from each other. Restoring a network link in this case will not make them re-join until the nodes are restarted and members specified in configuration file are connected again.

Then, as the Galera replication model truly cares about data consistency: once the inconsistency is detected, nodes that cannot execute row change statement due to a data difference – an emergency shutdown will be performed and the only way to bring the nodes back to the cluster is via the full SST

Based on material from Percona Database Performance Blog

This article is based on the blog post Galera replication - how to recover a PXC cluster by *Przemysław Malkowski*: https://www.percona.com/blog/2014/09/01/galera-replication-how-to-recover-a-pxc-cluster/

```
Last update: 2023-07-21
```

10.2 Configure a cluster on Red Hat-based distributions

This tutorial describes how to install and configure three Percona XtraDB Cluster nodes on Red Hat or CentOS 7 servers, using the packages from Percona repositories.

- Node 1
- Host name: perconal
- IP address: 192.168.70.71
- Node 2
- Host name: percona2
- IP address: 192.168.70.72
- Node 3
- Host name: percona3
- IP address: 192.168.70.73

10.2.1 Prerequisites

The procedure described in this tutorial requires the following:

- All three nodes have Red Hat or Red Hat or CentOS 7 installed.
- The firewall on all nodes is configured to allow connecting to ports 3306, 4444, 4567 and 4568.
- SELinux on all nodes is disabled.

Different from previous versions

The variable wsrep_sst_auth has been removed. Percona XtraDB Cluster 8.0 automatically creates the
system user mysql.pxc.internal.session. During SST, the user mysql.pxc.sst.user and the role
mysql.pxc.sst.role are created on the donor node.

10.2.2 Step 1. Installing PXC

Install Percona XtraDB Cluster on all three nodes as described in Installing Percona XtraDB Cluster on Red Hat Enterprise Linux or CentOS.

10.2.3 Step 2. Configuring the first node

Individual nodes should be configured to be able to bootstrap the cluster. For more information about bootstrapping the cluster, see Bootstrapping the First Node.

1. Make sure that the configuration file /etc/my.cnf on the first node (perconal) contains the following:

```
[mysqld]
datadir=/var/lib/mysql
user=mysql
# Path to Galera library
wsrep_provider=/usr/lib64/galera4/libgalera_smm.so
```

```
# Cluster connection URL contains the IPs of node#1, node#2 and node#3
wsrep_cluster_address=gcomm://192.168.70.71,192.168.70.72,192.168.70.73
# In order for Galera to work correctly binlog format should be ROW
binlog_format=ROW
# Using the MyISAM storage engine is not recommended.
default_storage_engine=InnoDB
# This InnoDB autoincrement locking mode is a requirement for Galera
innodb_autoinc_lock_mode=2
# Node 1 address
wsrep_node_address=192.168.70.71
# SST method
wsrep_sst_method=xtrabackup-v2
# Cluster name
wsrep_cluster_name=my_centos_cluster
```

2. Start the first node with the following command:

[root@perconal ~] # systemctl start mysql@bootstrap.service

The previous command will start the cluster with initial wsrep_cluster_address variable set to gcomm://. If the node or MySQL are restarted later, there will be no need to change the configuration file.

3. After the first node has been started, cluster status can be checked with the following command:

mysql> show status like 'wsrep%';

This output shows that the cluster has been successfully bootstrapped.

Expected output Y

| Variable_name | -++
 Value |
|---|---|
| | -++
 c2883338-834d-11e2-0800-03c9c68e41ec |
| <pre> wsrep_local_state wsrep_local_state_comment</pre> | 4
 Synced |
|
 wsrep_cluster_size
 wsrep_cluster_status
 wsrep_connected | 1
 Primary
 ON |
|
 wsrep_ready
+ | ON |
| 75 rows in set (0.00 sec) | |

Copy the automatically generated temporary password for the superuser account:

\$ sudo grep 'temporary password' /var/log/mysqld.log

Use this password to log in as root:

\$ mysql -u root -p

Change the password for the superuser account and log out. For example:

```
mysql> ALTER USER 'root'@'localhost' IDENTIFIED BY 'r00tP@$$';
```

Expected output 🗡

Query OK, 0 rows affected (0.00 sec)

10.2.4 Step 3. Configuring the second node

1. Make sure that the configuration file /etc/my.cnf on the second node (percona2) contains the following:

```
[mysqld]
datadir=/var/lib/mysql
user=mysql
# Path to Galera library
wsrep provider=/usr/lib64/galera4/libgalera smm.so
# Cluster connection URL contains IPs of node#1, node#2 and node#3
wsrep cluster address=gcomm://192.168.70.71,192.168.70.72,192.168.70.73
# In order for Galera to work correctly binlog format should be ROW
binlog format=ROW
# Using the MyISAM storage engine is not recommended
default storage engine=InnoDB
# This InnoDB auto increment locking mode is a requirement for Galera
innodb autoinc lock mode=2
# Node 2 address
wsrep node address=192.168.70.72
# Cluster name
wsrep cluster name=my centos cluster
# SST method
```

wsrep sst method=xtrabackup-v2

2. Start the second node with the following command:

[root@percona2 ~]# systemctl start mysql

3. After the server has been started, it should receive SST automatically. Cluster status can be checked on both nodes. The following is an example of status from the second node (percona2):

```
mysql> show status like 'wsrep%';
```

The output shows that the new node has been successfully added to the cluster.

| Expected output
Variable_name Value

 wsrep_cluster_status Primary |
| wsrep_cluster_size 2
 wsrep_cluster_status Primary |
| wsrep_cluster_status Primary |
| wsrep_connected ON |
| |
| wsrep_ready ON |

10.2.5 Step 4. Configuring the third node

1. Make sure that the MySQL configuration file /etc/my.cnf on the third node (percona3) contains the following:

```
[mysqld]
datadir=/var/lib/mysql
user=mysql
# Path to Galera library
wsrep provider=/usr/lib64/galera4/libgalera smm.so
# Cluster connection URL contains IPs of node#1, node#2 and node#3
wsrep cluster address=qcomm://192.168.70.71,192.168.70.72,192.168.70.73
# In order for Galera to work correctly binlog format should be ROW
binlog format=ROW
# Using the MyISAM storage engine is not recommended
default storage engine=InnoDB
# This InnoDB auto_increment locking mode is a requirement for Galera
innodb autoinc lock mode=2
# Node #3 address
wsrep node address=192.168.70.73
# Cluster name
wsrep cluster name=my centos cluster
# SST method
wsrep sst method=xtrabackup-v2
```

2. Start the third node with the following command:

```
[root@percona3 ~]# systemctl start mysql
```

3. After the server has been started, it should receive SST automatically. Cluster status can be checked on all three nodes. The following is an example of status from the third node (percona3):

mysql> show status like 'wsrep%';

The output confirms that the third node has joined the cluster.

| \equiv Expected output \checkmark | | |
|---------------------------------------|--------------------------------------|----|
| | | |
| Variable_name | Value | |
| | c2883338-834d-11e2-0800-03c9c68e41ec | : |
| wsrep_local_state | 4 | |
| <pre>wsrep_local_state_comment</pre> | Synced | Ì |
| ··· | | |
| wsrep_cluster_size | 3 | |
| wsrep_cluster_status | | |
| wsrep_connected | ON | |
| | | |
| wsrep_ready | ON | |
| + | -+ | -+ |
| 40 rows in set (0.01 sec) | | |
| | | |

10.2.6 Testing replication

To test replication, lets create a new database on second node, create a table for that database on the third node, and add some records to the table on the first node.

1. Create a new database on the second node:

```
mysql@percona2> CREATE DATABASE percona;
```

The following output confirms that a new database has been created:

Expected output Y

Query OK, 1 row affected (0.01 sec)

2. Switch to a newly created database:

mysql@percona3> USE percona;

The following output confirms that a database has been changed:

| Database changed | \equiv Expected output \checkmark | | |
|------------------|---------------------------------------|--|--|
| | Database changed | | |

3. Create a table on the third node:

mysql@percona3> CREATE TABLE example (node_id INT PRIMARY KEY, node_name VARCHAR(30));

The following output confirms that a table has been created:

Expected output ∽
Query OK, 0 rows affected (0.05 sec)

4. Insert records on the first node:

mysql@perconal> INSERT INTO percona.example VALUES (1, 'perconal');

The following output confirms that the records have been inserted:

| 1 | | |
|---|-------------------|--|
| 3 | Expected output ~ | |

Query OK, 1 row affected (0.02 sec)

5. Retrieve all the rows from that table on the second node:

mysql@percona2> SELECT * FROM percona.example;

The following output confirms that all the rows have been retrieved:

```
Expected output ~

f+----+
i node_id | node_name |
t+----++
i 1 | perconal |
t+---+++
i row in set (0.00 sec)
```

This simple procedure should ensure that all nodes in the cluster are synchronized and working as intended.

Last update: 2023-07-21

10.3 Configure a cluster on Debian or Ubuntu

This tutorial describes how to install and configure three Percona XtraDB Cluster nodes on Ubuntu 14 LTS servers, using the packages from Percona repositories.

- Node 1
- Host name: pxc1
- IP address: 192.168.70.61
- Node 2
- Host name: pxc2
- IP address: 192.168.70.62
- Node 3
- Host name: pxc3
- IP address: 192.168.70.63

10.3.1 Prerequisites

The procedure described in this tutorial requires he following:

- All three nodes have Ubuntu 14 LTS installed.
- Firewall on all nodes is configured to allow connecting to ports 3306, 4444, 4567 and 4568.
- AppArmor profile for MySQL is disabled.

10.3.2 Step 1. Install PXC

Install Percona XtraDB Cluster on all three nodes as described in Installing Percona XtraDB Cluster on Debian or Ubuntu.

🖍 Note

Debian/Ubuntu installation prompts for root password. For this tutorial, set it to Passw0rd. After the packages have been installed, mysqld will start automatically. Stop mysqld on all three nodes using sudo systemctl stop mysql.

10.3.3 Step 2. Configure the first node

Individual nodes should be configured to be able to bootstrap the cluster. For more information about bootstrapping the cluster, see Bootstrapping the First Node.

1. Make sure that the configuration file /etc/mysql/my.cnf for the first node (pxcl) contains the following:

```
[mysqld]
datadir=/var/lib/mysql
user=mysql
# Path to Galera library
wsrep_provider=/usr/lib/libgalera_smm.so
```

```
# Cluster connection URL contains the IPs of node#1, node#2 and node#3
wsrep_cluster_address=gcomm://192.168.70.61,192.168.70.62,192.168.70.63
# In order for Galera to work correctly binlog format should be ROW
binlog_format=ROW
# Using the MyISAM storage engine is not recommended
default_storage_engine=InnoDB
# This InnoDB autoincrement locking mode is a requirement for Galera
innodb_autoinc_lock_mode=2
# Node #1 address
wsrep_node_address=192.168.70.61
# SST method
wsrep_sst_method=xtrabackup-v2
# Cluster name
```

2. Start the first node with the following command:

wsrep_cluster_name=my_ubuntu_cluster

[root@pxc1 ~]# systemctl start mysql@bootstrap.service

This command will start the first node and bootstrap the cluster.

3. After the first node has been started, cluster status can be checked with the following command:

mysql> show status like 'wsrep%';

The following outut shows the cluste status:

| \equiv Expected output \checkmark | | |
|---|--------------------------------------|----|
| | 1 | |
| Variable_name |
 Value
-+ | |
| <pre> wsrep_local_state_uuid</pre> | b598af3e-ace3-11e2-0800-3e90eb9cd5d3 | |
| <pre> wsrep_local_state wsrep_local_state_comment</pre> | | |
|
 wsrep_cluster_size
 wsrep_cluster_status
 wsrep connected | 1
 Primary
 ON | |
| wsrep_connected

 wsrep_ready | ON | |
| +
75 rows in set (0.00 sec) | -+ | -+ |

This output shows that the cluster has been successfully bootstrapped.

To perform State Snapshot Transfer using XtraBackup, set up a new user with proper privileges:

```
mysql@pxc1> CREATE USER 'sstuser'@'localhost' IDENTIFIED BY 's3cretPass';
mysql@pxc1> GRANT PROCESS, RELOAD, LOCK TABLES, REPLICATION CLIENT ON *.* TO
```

```
'sstuser'@'localhost';
mysql@pxc1> FLUSH PRIVILEGES;
```

🧪 Note

MySQL root account can also be used for performing SST, but it is more secure to use a different (non-root) user for this.

10.3.4 Step 3. Configure the second node

1. Make sure that the configuration file /etc/mysql/my.cnf on the second node (pxc2) contains the following:

```
[mysqld]
datadir=/var/lib/mysql
user=mysql
# Path to Galera library
wsrep_provider=/usr/lib/libgalera_smm.so
# Cluster connection URL contains IPs of node#1, node#2 and node#3
wsrep cluster address=gcomm://192.168.70.61,192.168.70.62,192.168.70.63
# In order for Galera to work correctly binlog format should be ROW
binlog format=ROW
# Using the MyISAM storage engine is not recommended
default storage engine=InnoDB
# This InnoDB autoincrement locking mode is a requirement for Galera
innodb_autoinc_lock_mode=2
# Node #2 address
wsrep node address=192.168.70.62
# Cluster name
wsrep cluster name=my ubuntu cluster
# SST method
wsrep sst method=xtrabackup-v2
```

2. Start the second node with the following command:

[root@pxc2 ~]# systemctl start mysql

3. After the server has been started, it should receive SST automatically. Cluster status can now be checked on both nodes. The following is an example of status from the second node (pxc2):

127 of 240

mysql> show status like 'wsrep%';

The following output shows that the new node has been successfully added to the cluster.

| | -+ | -+ |
|--------------------------------------|--------------------------------------|----|
| Variable_name | Value | |
| wsrep_local_state_uuid | b598af3e-ace3-11e2-0800-3e90eb9cd5d3 | |
| <pre>wsrep_local_state</pre> | 4 | |
| <pre>wsrep_local_state_comment</pre> | Synced | |
|
wsrep_cluster_size | 2 | |
| wsrep_cluster_status | Primary | |
| <pre>wsrep_connected</pre> | ON | |
| wsrep_ready | ON | 1 |

10.3.5 Step 4. Configure the third node

1. Make sure that the MySQL configuration file /etc/mysql/my.cnf on the third node (pxc3) contains the following:

```
[mysqld]
datadir=/var/lib/mysql
user=mysql
# Path to Galera library
wsrep_provider=/usr/lib/libgalera_smm.so
# Cluster connection URL contains IPs of node#1, node#2 and node#3
wsrep_cluster_address=gcomm://192.168.70.61,192.168.70.62,192.168.70.63
# In order for Galera to work correctly binlog format should be ROW
binlog_format=ROW
# Using the MyISAM storage engine is not recommended
default_storage_engine=InnoDB
# This InnoDB autoincrement locking mode is a requirement for Galera
innodb_autoinc_lock_mode=2
# Node #3 address
wsrep_node_address=192.168.70.63
# Cluster name
wsrep_cluster_name=my_ubuntu_cluster
# SST method
wsrep_sst_method=xtrabackup-v2
```

2. Start the third node with the following command:

```
[root@pxc3 ~]# systemctl start mysql
```

3. After the server has been started, it should receive SST automatically. Cluster status can be checked on all nodes. The following is an example of status from the third node (pxc3):

mysql> show status like 'wsrep%';

The following output confirms that the third node has joined the cluster.

| Expected output | |
|--|--------------------------------------|
| | |
| +
 Variable_name
+ | -+ |
| <pre>wsrep_local_state_uuid</pre> | b598af3e-ace3-11e2-0800-3e90eb9cd5d3 |
| <pre>wsrep_local_state</pre> | 4 |
| <pre> wsrep_local_state_comment</pre> | Synced |
| wsrep_cluster_size | 3 |
| <pre>wsrep_cluster_status</pre> | Primary |
| wsrep_connected | ON |
| wsrep_ready
+ | ON |
| 40 rows in set (0.01 sec) | |

10.3.6 Test replication

To test replication, lets create a new database on the second node, create a table for that database on the third node, and add some records to the table on the first node.

1. Create a new database on the second node:

mysql@percona2> CREATE DATABASE percona;

The following output confirms that a new database has been created:

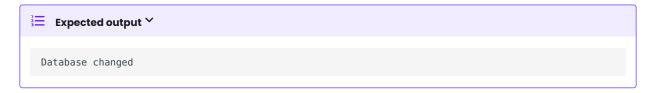

Expected output Y

Query OK, 1 row affected (0.01 sec)

2. Switch to a newly created database:

mysql@percona3> USE percona;

The following output confirms that a database has been changed:

3. Create a table on the third node:

mysql@percona3> CREATE TABLE example (node_id INT PRIMARY KEY, node_name VARCHAR(30));

The following output confirms that a table has been created:

Expected output ✓
Query 0K, 0 rows affected (0.05 sec)

4. Insert records on the first node:

mysql@perconal> INSERT INTO percona.example VALUES (1, 'perconal');

The following output confirms that the records have been inserted:

| 12
3 | Expected output \checkmark |
|---------|------------------------------|
| | |

Query OK, 1 row affected (0.02 sec)

5. Retrieve all the rows from that table on the second node:

mysql@percona2> SELECT * FROM percona.example;

The following output confirms that all the rows have been retrieved:

```
Expected output ~

f+-----+
i node_id | node_name |
+----++
i 1 | perconal |
+----++
i row in set (0.00 sec)
```

This simple procedure should ensure that all nodes in the cluster are synchronized and working as intended.

Last update: 2023-07-21

10.4 Set up Galera arbitrator

The size of a cluster increases when a node joins the cluster and decreases when a node leaves. A cluster reacts to replication problems with inconsistency voting. The size of the cluster determines the required votes to achieve a quorum. If a node no longer responds and is disconnected from the cluster the remaining nodes vote. The majority of the nodes that vote are considered to be in the cluster.

The arbitrator is important if you have an even number of nodes remaining in the cluster. The arbitrator keeps the number of nodes as an odd number, which avoids the split-brain situation.

A Galera Arbitrator is a lightweight member of a **Percona XtraDB Cluster**. This member can vote but does not do any replication and is not included in flow control calculations. The Galera Arbitrator is a separate daemon called garbd. You can start this daemon separately from the cluster and run this daemon either as a service or from the shell. You cannot configure this daemon using the my.cnf file.

For more information on how to set up a cluster you can read in the Configuring Percona XtraDB Cluster on Ubuntu or Configuring Percona XtraDB Cluster on CentOS manuals.

10.4.1 Installation

Galera Arbitrator does not need a dedicated server and can be installed on a machine running other applications. The server must have good network connectivity.

Galera Arbitrator can be installed from Percona's repository on Debian/Ubuntu distributions with the following command:

root@ubuntu:~# apt install percona-xtradb-cluster-garbd

Galera Arbitrator can be installed from Percona's repository on RedHat or derivative distributions with the following command:

[root@centos ~]# yum install percona-xtradb-cluster-garbd

10.4.2 Start garbd and configuration

On **Percona XtraDB Cluster** 8.0, SSL is enabled by default. To run the Galera Arbitrator, you must copy the SSL certificates and configure garbd to use the certificates.

It is necessary to specify the cipher. In this example, it is [AES128-5HA256]. If you do not specify the cipher, an error occurs with a "Terminate called after throwing an instance of 'gnu::NotSet'" message.

For more information, see socket.ssl_cipher

When starting from the shell, you can set the parameters from the command line or edit the configuration file. This is an example of starting from the command line:

```
$ garbd --group=my_ubuntu_cluster \
--address="gcomm://192.168.70.61:4567, 192.168.70.62:4567, 192.168.70.63:4567" \
--option="socket.ssl=YES; socket.ssl_key=/etc/ssl/mysql/server-key.pem; \
socket.ssl_cert=/etc/ssl/mysql/server-cert.pem; \
socket.ssl_ca=/etc/ssl/mysql/ca.pem; \
socket.ssl_cipher=AES128-SHA256"
```

To avoid entering the options each time you start garbd, edit the options in the configuration file. To configure *Galera Arbitrator* on *Ubuntu/Debian*, edit the /etc/default/garb file. On RedHat or derivative distributions, the configuration can be found in /etc/sysconfig/garb file.

The configuration file should look like this after the installation and before you have added your parameters:

```
# Copyright (C) 2013-2015 Codership Oy
# This config file is to be sourced by garb service script.
# REMOVE THIS AFTER CONFIGURATION
# A comma-separated list of node addresses (address[:port]) in the cluster
# GALERA_NODES=""
# Galera cluster name, should be the same as on the rest of the nodes.
# GALERA_GROUP=""
# Optional Galera internal options string (e.g. SSL settings)
# see http://galeracluster.com/documentation-webpages/galeraparameters.html
# GALERA_OPTIONS=""
# Log file for garbd. Optional, by default logs to syslog
# Deprecated for Cent0S7, use journalctl to query the log for garbd
# LOG FILE=""
```

Add the parameter information about the cluster. For this document, we use the cluster information from Configuring Percona XtraDB Cluster on Ubuntu.

```
🖍 Note
```

Please note that you need to remove the # REMOVE THIS AFTER CONFIGURATION line before you can start the service.

```
# This config file is to be sourced by garb service script.
# A comma-separated list of node addresses (address[:port]) in the cluster
GALERA_NODES="192.168.70.61:4567, 192.168.70.62:4567, 192.168.70.63:4567"
# Galera cluster name, should be the same as on the rest of the nodes.
GALERA_GROUP="my_ubuntu_cluster"
# Optional Galera internal options string (e.g. SSL settings)
# see http://galeracluster.com/documentation-webpages/galeraparameters.html
# GALERA_OPTIONS="socket.ssl_cert=/etc/ssl/mysql/server-key.pem;socket./etc/ssl/mysql/
server-key.pem"
# Log file for garbd. Optional, by default logs to syslog
```

```
# Log file for garbd. Uptional, by default logs to systog
# Deprecated for CentOS7, use journalctl to query the log for garbd
# LOG FILE="/var/log/garbd.log"
```

You can now start the Galera Arbitrator daemon (garbd) by running:

On Debian or Ubuntu On Red Hat Enterprise Linux or CentOS

root@server:~# service garbd start

Expected output Y

[ok] Starting /usr/bin/garbd: :.

🖍 Note

On systems that run systemd as the default system and service manager, use systemctl instead of service to invoke the command. Currently, both are supported.

root@server:~# systemctl start garb

root@server:~# service garb start

Expected output 🗡

[ok] Starting /usr/bin/garbd: :.

Additionally, you can check the arbitrator status by running:

On Debian or Ubuntu On Red Hat Enterprise Linux or CentOS

root@server:~# service garbd status

Expected output 🗡

[ok] garb is running.

root@server:~# service garb status

Expected output 🗡

[ok] garb is running.

```

```

10.5 How to set up a three-node cluster on a single box

This tutorial describes how to set up a 3-node cluster on a single physical box.

For the purposes of this tutorial, assume the following:

- The local IP address is 192.168.2.21.
- Percona XtraDB Cluster is extracted from binary tarball into /usr/local/Percona-XtraDB-Cluster-8.0.x86_64

To set up the cluster:

- 1. Create three MySQL configuration files for the corresponding nodes:
- /etc/my.4000.cnf

```
[mysqld]
port = 4000
socket=/tmp/mysql.4000.sock
datadir=/data/bench/d1
basedir=/usr/local/Percona-XtraDB-Cluster-8.0.x86 64
user=mysql
log error=error.log
binlog format=ROW
wsrep cluster address='gcomm://192.168.2.21:5030,192.168.2.21:6030'
wsrep provider=/usr/local/Percona-XtraDB-Cluster-8.0.x86 64/lib/libgalera smm.so
wsrep sst receive address=192.168.2.21:4020
wsrep node incoming address=192.168.2.21
wsrep cluster name=trimethylxanthine
wsrep provider options = "gmcast.listen addr=tcp://192.168.2.21:4030;"
wsrep sst method=xtrabackup-v2
wsrep node name=node4000
innodb autoinc lock mode=2
```

• /etc/my.5000.cnf

```
[mysqld]
port = 5000
socket=/tmp/mysql.5000.sock
datadir=/data/bench/d2
basedir=/usr/local/Percona-XtraDB-Cluster-8.0.x86 64
user=mysql
log error=error.log
binlog_format=ROW
wsrep_cluster_address='gcomm://192.168.2.21:4030,192.168.2.21:6030'
wsrep provider=/usr/local/Percona-XtraDB-Cluster-8.0.x86 64/lib/libgalera smm.so
wsrep sst receive address=192.168.2.21:5020
wsrep node incoming address=192.168.2.21
wsrep cluster name=trimethylxanthine
wsrep provider options = "gmcast.listen addr=tcp://192.168.2.21:5030;"
wsrep sst method=xtrabackup-v2
wsrep_node_name=node5000
```

innodb_autoinc_lock_mode=2

• /etc/my.6000.cnf

[mysqld] port = 6000 socket=/tmp/mysql.6000.sock datadir=/data/bench/d3

```
basedir=/usr/local/Percona-XtraDB-Cluster-8.0.x86_64
user=mysql
log_error=error.log
binlog_format=ROW
wsrep_cluster_address='gcomm://192.168.2.21:4030,192.168.2.21:5030'
wsrep_provider=/usr/local/Percona-XtraDB-Cluster-8.0.x86_64/lib/libgalera_smm.so
wsrep_sst_receive_address=192.168.2.21:6020
wsrep_node_incoming_address=192.168.2.21
wsrep_cluster_name=trimethylxanthine
wsrep_provider_options = "gmcast.listen_addr=tcp://192.168.2.21:6030;"
wsrep_sst_method=xtrabackup-v2
wsrep_node_name=node6000
innodb_autoinc_lock_mode=2
```

2. Create three data directories for the nodes:

- /data/bench/d1
- /data/bench/d2
- /data/bench/d3

3. Start the first node using the following command (from the Percona XtraDB Cluster install directory):

\$ bin/mysqld_safe --defaults-file=/etc/my.4000.cnf --wsrep-new-cluster

If the node starts correctly, you should see the following output:

Expected output 🗡

```
111215 19:01:49 [Note] WSREP: Shifting JOINED -> SYNCED (TO: 0)
111215 19:01:49 [Note] WSREP: New cluster view: global state: 4c286ccc-2792-11e1-0800-94bd91e32efa:
0, view# 1: Primary, number of nodes: 1, my index: 0, protocol version 1
```

To check the ports, run the following command:

| \$ netsta | t -anp | grep mysqld | | |
|-----------|--------|-----------------------------|-----------------------|--------|
| tcp | 0 | 0 192 .168.2.21:4030 | <mark>0</mark> .0.0:* | LISTEN |
| 21895/my | sqld | | | |
| tcp | 0 | 0.0.0:4000 | <mark>0</mark> .0.0:* | LISTEN |
| 21895/my | sqld | | | |

4. Start the second and third nodes:

```
bin/mysqld_safe --defaults-file=/etc/my.5000.cnf
bin/mysqld safe --defaults-file=/etc/my.6000.cnf
```

If the nodes start and join the cluster successful, you should see the following output:

```
111215 19:22:26 [Note] WSREP: Shifting JOINER -> JOINED (TO: 2)
111215 19:22:26 [Note] WSREP: Shifting JOINED -> SYNCED (TO: 2)
111215 19:22:26 [Note] WSREP: Synchronized with group, ready for connections
```

To check the cluster size, run the following command:

\$ mysql -h127.0.0.1 -P6000 -e "show global status like 'wsrep cluster size';"

135 of 240

Expected output Y

```
+ Variable_name | Value |
+ Variable_name | Value |
+ Value |
+ Value | Value |
+ Value | Value |
+ Value | Value | Value |
```

After that you can connect to any node and perform queries, which will be automatically synchronized with other nodes. For example, to create a database on the second node, you can run the following command:

```
$ mysql -h127.0.0.1 -P5000 -e "CREATE DATABASE hello_peter"
```

Last update: 2023-07-21

10.6 How to set up a three-node cluster in EC2 environment

This manual assumes you are running three EC2 instances with Red Hat Enterprise Linux 7 64-bit.

- node1: 10.93.46.58
- node2: 10.93.46.59
- node3: 10.93.46.60

Recommendations on launching EC2 instances

- 1. Select instance types that support Enhanced Networking functionality. Good network performance critical for synchronous replication used in Percona XtraDB Cluster.
- 2. When adding instance storage volumes, choose the ones with good I/O performance:
- instances with NVMe are preferred
- GP2 SSD are preferred to GP3 SSD volume types due to I/O latency
- over sized GP2 SSD are preferred to IO1 volume types due to cost
- 3. Attach Elastic network interfaces with static IPs or assign Elastic IP addresses to your instances. Thereby IP addresses are preserved on instances in case of reboot or restart. This is required as each Percona XtraDB Cluster member includes the wsrep_cluster_address option in its configuration which points to other cluster members.
- 4. Launch instances in different availability zones to avoid cluster downtime in case one of the zones experiences power loss or network connectivity issues.

🖍 See also

Amazon EC2 Documentation: https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/EC2_GetStarted.html

To set up Percona XtraDB Cluster:

- 1. Remove Percona XtraDB Cluster and Percona Server for MySQL packages for older versions:
- Percona XtraDB Cluster 5.6, 5.7
- Percona Server for MySQL 5.6, 5.7
- 2. Install Percona XtraDB Cluster as described in Installing Percona XtraDB Cluster on Red Hat Enterprise Linux and CentOS.
- 3. Create data directories:

```
$ mkdir -p /mnt/data
$ mysql install db --datadir=/mnt/data --user=mysql
```

4. Stop the firewall service:

```
$ service iptables stop
```

🖍 Note

Alternatively, you can keep the firewall running, but open ports 3306, 4444, 4567, 4568. For example to open port 4567 on 192.168.0.1:

iptables -A INPUT -i eth0 -p tcp -m tcp --source 192.168.0.1/24 --dport 4567 -j ACCEPT

5. Create /etc/my.cnf files:

Contents of the configuration file on the first node:

```
[mysqld]
datadir=/mnt/data
user=mysql
binlog_format=ROW
wsrep_provider=/usr/lib64/libgalera_smm.so
wsrep_cluster_address=gcomm://10.93.46.58,10.93.46.59,10.93.46.60
wsrep_cluster_name=trimethylxanthine
wsrep_sst_method=xtrabackup-v2
wsrep_node_name=node1
innodb autoinc lock mode=2
```

For the second and third nodes change the following lines:

wsrep_node_name=node2

wsrep_node_name=node3

6. Start and bootstrap Percona XtraDB Cluster on the first node:

```
[root@pxc1 ~]# systemctl start mysql@bootstrap.service
```

Expected output Y

```
2014-01-30 11:52:35 23280 [Note] /usr/sbin/mysqld: ready for connections.
Version: '...' socket: '/var/lib/mysql/mysql.sock' port: 3306 Percona XtraDB Cluster (GPL),
Release ..., Revision ..., wsrep_version
```

7. Start the second and third nodes:

\$ sudo systemctl start mysql

Expected output 🗡 ... [Note] WSREP: Flow-control interval: [28, 28] ... [Note] WSREP: Restored state OPEN -> JOINED (2) ... [Note] WSREP: Member 2 (perconal) synced with group. ... [Note] WSREP: Shifting JOINED -> SYNCED (TO: 2) ... [Note] WSREP: New cluster view: global state: 4827a206-876b-11e3-911c-3e6a77d54953:2, view# 7: Primary, number of nodes: 3, my index: 2, protocol version 2 ... [Note] WSREP: SST complete, seqno: 2 ... [Note] Plugin 'FEDERATED' is disabled. ... [Note] InnoDB: The InnoDB memory heap is disabled ... [Note] InnoDB: Mutexes and rw_locks use GCC atomic builtins ... [Note] InnoDB: Compressed tables use zlib 1.2.3 ... [Note] InnoDB: Using Linux native AIO ... [Note] InnoDB: Not using CPU crc32 instructions ... [Note] InnoDB: Initializing buffer pool, size = 128.0M ... [Note] InnoDB: Completed initialization of buffer pool ... [Note] InnoDB: Highest supported file format is Barracuda. ... [Note] InnoDB: 128 rollback segment(s) are active. ... [Note] InnoDB: Waiting for purge to start .. [Note] InnoDB: Percona XtraDB (http://www.percona.com) ... started; log sequence number 1626341 ... [Note] RSA private key file not found: /var/lib/mysql//private key.pem. Some authentication plugins will not work. ... [Note] RSA public key file not found: /var/lib/mysql//public_key.pem. Some authentication plugins will not work. ... [Note] Server hostname (bind-address): '*'; port: 3306 ... [Note] IPv6 is available. ... [Note] - '::' resolves to '::'; ... [Note] Server socket created on IP: '::'. ... [Note] Event Scheduler: Loaded 0 events ... [Note] /usr/sbin/mysqld: ready for connections.

... [Note] /usr/sbin/mysqld: ready for connections. Version: '...' socket: '/var/lib/mysql/mysql.sock' port: 3306 Percona XtraDB Cluster (GPL), Release ..., Revision ..., wsrep_version ... [Note] WSREP: inited wsrep sidno 1 ... [Note] WSREP: wsrep_notify_cmd is not defined, skipping notification. ... [Note] WSREP: REPL Protocols: 5 (3, 1) ... [Note] WSREP: Assign initial position for certification: 2, protocol version: 3 ... [Note] WSREP: Service thread queue flushed. ... [Note] WSREP: Synchronized with group, ready for connections

When all nodes are in SYNCED state, your cluster is ready.

8. You can try connecting to MySQL on any node and create a database:

```
$ mysql -uroot
> CREATE DATABASE hello tom;
```

The new database will be propagated to all nodes.

Last update: 2023-07-21

10.7 Load balancing with HAProxy

This manual describes how to configure HAProxy to work with Percona XtraDB Cluster.

Start by installing HAProxy on a node that you intend to use for load balancing. The operating systems that support Percona XtraDB Cluster provide the haproxy package and you can install it using the package manager.

Debian or Ubuntu

```
```{.bash data-prompt="$"}
$ sudo apt update
$ sudo apt install haproxy
```
```

Red Hat or CentOS:

```
```{.bash data-prompt="$"}
$ sudo yum update
$ sudo yum install haproxy
```
```

Supported versions of HAProxy

The lowest supported version of HAProxy is 1.4.20.

To start HAProxy, use the haproxy command. You may pass any number of configuration parameters on the command line. To use a configuration file, use the -f option.

```
$ # Passing one configuration file
$ sudo haproxy -f haproxy-1.cfg
$ # Passing multiple configuration files
$ sudo haproxy -f haproxy-1.cfg haproxy-2.cfg
$ # Passing a directory
$ sudo haproxy -f conf-dir
```

You can pass the name of an existing configuration file or a directory. HAProxy includes all files with the *.cfg* extension in the the supplied directory. Another way to pass multiple files is to use -f multiple times.

Example of the HAProxy configuration file ```{.text .no-copy} global log 127.0.0.1 local0 log 127.0.0.1 local1 notice maxconn 4096 uid 99 gid 99 daemon #debug #quiet defaults log global mode http option tcplog option dontlognull retries 3 redispatch maxconn 2000 contimeout 5000 clitimeout 50000 srvtimeout 50000 listen mysql-cluster 0.0.0.0:3306 mode tcp balance roundrobin option mysql-check user root server db01 10.4.29.100:3306 check server db02 10.4.29.99:3306 check server db03 10.4.29.98:3306 check

Options set in the configuration file

| HAProxy option (with links to
HAProxy documentation) | Description | |
|---|---|--|
| global | A section in the configuration file for process-wide parameters | |
| defaults | A section in the configuration file for default parameters for all other following sections | |
| listen | A section in the configuration file that defines a complete proxy with its frontend and backend parts combined in one section | |
| balance | Load balancing algorithm to be used in a backend | |
| clitimeout | Set the maximum inactivity time on the client side | |
| contimeout | Set the maximum time to wait for a connection attempt to a server to succeed. | |
| daemon | Makes the process fork into background (recommended mode of operation) | |
| gid | Changes the process' group ID to <number></number> | |
| log | Adds a global syslog server | |
| maxconn | Sets the maximum per-process number of concurrent connections to <number></number> | |

| HAProxy option (with links to
HAProxy documentation) | Description | |
|---|---|--|
| mode | Set the running mode or protocol of the instance | |
| option dontlognull | Disable logging of null connections | |
| option tcplog | Enable advanced logging of TCP connections with session state and timers | |
| redispatch | Enable or disable session redistribution in case of connection failure | |
| retries | Set the number of retries to perform on a server after a connection failure | |
| server | Declare a server in a backend | |
| srvtimeout | Set the maximum inactivity time on the server side | |
| uid | Changes the process' user ID to <number></number> | |

With this configuration, HAProxy will balance the load between three nodes. In this case, it only checks if mysqld listens on port 3306, but it doesn't take into an account the state of the node. So it could be sending queries to the node that has mysqld running even if it's in JOINING or DISCONNECTED state.

To check the current status of a node we need a more complex check. This idea was taken from codershipteam google groups.

To implement this setup, you will need two scripts:

• clustercheck (located in /usr/local/bin) and a config for xinetd

• mysqlchk (located in /etc/xinetd.d) on each node

Both scripts are available in binaries and source distributions of Percona XtraDB Cluster.

Change the /etc/services file by adding the following line on each node:

mysqlchk

9200/tcp

mysqlchk

```
```{.text .no-copy}
this config needs haproxy-1.4.20
global
 log 127.0.0.1 local0
 log 127.0.0.1 local1 notice
 maxconn 4096
 uid 99
 gid 99
 #daemon
 debug
 #quiet
defaults
 log
 global
 mode
 http
 option tcplog
 option dontlognull
 retries 3
 redispatch
 maxconn 2000
 contimeout 5000
clitimeout 50000
srvtimeout 50000
 contimeout
 5000
listen mysql-cluster 0.0.0.0:3306
 mode tcp
 balance roundrobin
 option httpchk
 server db01 10.4.29.100:3306 check port 9200 inter 12000 rise 3 fall 3

 server db03 10.4.29.98:3306 check port 9200 inter 12000 rise 3 fall 3
```

#### 🜢 Important

In Percona XtraDB Cluster 8.0, the default authentication plugin is caching\_sha2\_password. HAProxy does not support this authentication plugin. Create a mysql user using the mysql\_native\_password authentication plugin.

mysql> CREATE USER 'haproxy\_user'@'%' IDENTIFIED WITH mysql\_native\_password by '\$3Kr\$t';

Example of the HAProxy configuration file

Last update: 2023-07-21

# 10.8 Load balance with ProxySQL

ProxySQL is a high-performance SQL proxy. ProxySQL runs as a daemon watched by a monitoring process. The process monitors the daemon and restarts it in case of a crash to minimize downtime.

The daemon accepts incoming traffic from MySQL clients and forwards it to backend MySQL servers.

The proxy is designed to run continuously without needing to be restarted. Most configuration can be done at runtime using queries similar to SQL statements in the ProxySQL admin interface. These include runtime parameters, server grouping, and traffic-related settings.

# See also ProxySQL Documentation

ProxySQL v2 natively supports Percona XtraDB Cluster. With this version, proxysql-admin tool does not require any custom scripts to keep track of Percona XtraDB Cluster status.

## 🗴 Important

In version 8.0, Percona XtraDB Cluster does not support ProxySQL vl.

## 10.8.1 Manual configuration

This section describes how to configure ProxySQL with three Percona XtraDB Cluster nodes.

Node	Host Name	IP address
Node 1	рхс1	192.168.70.71
Node 2	pxc2	192.168.70.72
Node 3	рхс3	192.168.70.73
Node 4	proxysql	192.168.70.74

ProxySQL can be configured either using the /etc/proxysql.cnf file or through the admin interface. The admin interface is recommended because this interface can dynamically change the configuration without restarting the proxy.

To connect to the ProxySQL admin interface, you need a <code>mysql</code> client. You can either connect to the admin interface from Percona XtraDB Cluster nodes that already have the <code>mysql</code> client installed (Node 1, Node 2, Node 3) or install the client on Node 4 and connect locally. For this tutorial, install Percona XtraDB Cluster on Node 4:

## Changes in the installation procedure

In Percona XtraDB Cluster 8.0, ProxySQL is not installed automatically as a dependency of the perconaxtradb-cluster-client-8.0 package. You should install the proxysql package separately.

ProxySQL has multiple versions in the version 2 series.

• On Debian or Ubuntu for ProxySQL 2.x:

```
root@proxysql:~# apt install percona-xtradb-cluster-client
root@proxysql:~# apt install proxysql2
```

• On Red Hat Enterprise Linux or CentOS for ProxySQL 2.x:

```
$ sudo yum install Percona-XtraDB-Cluster-client-80
$ sudo yum install proxysql2
```

To connect to the admin interface, use the credentials, host name and port specified in the global variables.

#### 🛕 Warning

Do not use default credentials in production!

The following example shows how to connect to the ProxySQL admin interface with default credentials:

root@proxysql:~# mysql -u admin -padmin -h 127.0.0.1 -P 6032

#### Expected output

```
Welcome to the MySQL monitor. Commands end with ; or \g.
Your MySQL connection id is 2
Server version: 5.5.30 (ProxySQL Admin Module)
```

Copyright (c) 2009-2020 Percona LLC and/or its affiliates Copyright (c) 2000, 2020, Oracle and/or its affiliates. All rights reserved.

```
Oracle is a registered trademark of Oracle Corporation and/or its affiliates. Other names may be trademarks of their respective owners.
```

Type 'help;' or '\h' for help. Type '\c' to clear the current input statement.

mysql@proxysql>

To see the ProxySQL databases and tables use the following commands:

mysql@proxysql> SHOW DATABASES;

The following output shows the ProxySQL databases:

mysql@proxysql> SHOW TABLES;

The following output shows the ProxySQL tables:

For more information about admin databases and tables, see Admin Tables

## 🖍 Note

The ProxySQL configuration can reside in the following areas:

- MEMORY (your current working place)
- RUNTIME (the production settings)
- DISK (durable configuration, saved inside an SQLITE database)

When you change a parameter, you change it in MEMORY area. This ability is by design and lets you test the changes before pushing the change to production (RUNTIME), or save the change to disk.

#### Add cluster nodes to ProxySQL

To configure the backend Percona XtraDB Cluster nodes in ProxySQL, insert corresponding records into the mysql\_servers table.

#### / Note

ProxySQL uses the concept of *hostgroups* to group cluster nodes. This enables you to balance the load in a cluster by routing different types of traffic to different groups. There are many ways you can configure hostgroups (for example, source and replicas, read and write load, etc.) and a every node can be a member of multiple hostgroups.

This example adds three Percona XtraDB Cluster nodes to the default hostgroup (0), which receives both write and read traffic:

```
mysql@proxysql> INSERT INTO mysql_servers(hostgroup_id, hostname, port) VALUES
(0,'192.168.70.71',3306);
mysql@proxysql> INSERT INTO mysql_servers(hostgroup_id, hostname, port) VALUES
(0,'192.168.70.72',3306);
mysql@proxysql> INSERT INTO mysql_servers(hostgroup_id, hostname, port) VALUES
(0,'192.168.70.73',3306);
```

#### To see the nodes:

mysql@proxysql> SELECT \* FROM mysql\_servers;

#### The following output shows the list of nodes:

eted output         ted output
<pre>roup_id   hostname   port   status   weight   compression   max_connections   .ication_lag   use_ssl   max_latency_ms   comment   +   192.168.70.71   3306   ONLINE   1   0   1000     0   0   0   1000     192.168.70.72   3306   ONLINE   1   0   1000     0   0   0   1000     192.168.70.73   3306   ONLINE   1   0   1000  </pre>

## Create ProxySQL monitoring user

To enable monitoring of Percona XtraDB Cluster nodes in ProxySQL, create a user with USAGE privilege on any node in the cluster and configure the user in ProxySQL.

The following example shows how to add a monitoring user on Node 2:

```
mysql@pxc2> CREATE USER 'proxysql'@'%' IDENTIFIED WITH mysql_native_password by '$3Kr$t';
mysql@pxc2> GRANT USAGE ON *.* TO 'proxysql'@'%';
```

The following example shows how to configure this user on the ProxySQL node:

```
mysql@proxysql> UPDATE global_variables SET variable_value='proxysql'
 WHERE variable_name='mysql-monitor_username';
mysql@proxysql> UPDATE global_variables SET variable_value='ProxySQLPa55'
 WHERE variable name='mysql-monitor password';
```

To load this configuration at runtime, issue a LOAD command. To save these changes to disk (ensuring that they persist after ProxySQL shuts down), issue a SAVE command.

mysql@proxysql> LOAD MYSQL VARIABLES TO RUNTIME; mysql@proxysql> SAVE MYSQL VARIABLES TO DISK;

To ensure that monitoring is enabled, check the monitoring logs:

mysql@proxysql> SELECT \* FROM monitor.mysql\_server\_connect\_log ORDER BY time\_start\_us DESC LIMIT 6;

Expected outpu	ıt			
hostname	port   t	ime_start_us	+ connect_success_time	connect_error
192.168.70.71   192.168.70.72   192.168.70.73   192.168.70.71   192.168.70.72   192.168.70.73	3306   1   3306   1   3306   1   3306   1   3306   1   3306   1	469635762434625 469635762434625 469635762434625 469635642434517 469635642434517 469635642434517	1695   1779   1627   1557   2737   1447	NULL   NULL   NULL   NULL   NULL   NULL +

mysql> SELECT \* FROM monitor.mysql\_server\_ping\_log ORDER BY time\_start\_us DESC LIMIT 6;

Expected output	t				
			+.		L
hostname	port	time_start_us		<pre>ping_success_time</pre>	ping_error
192.168.70.71   192.168.70.72   192.168.70.73   192.168.70.71	3306   3306   3306   3306	1469635762416190 1469635762416190 1469635762416190 1469635702416062 1469635702416062	I	948 803 711 783 631	NULL     NULL     NULL     NULL     NULL
'	+	1469635702416062		542	NULL   ++

The previous examples show that ProxySQL is able to connect and ping the nodes you have added.

To enable monitoring of these nodes, load them at runtime:

mysql@proxysql> LOAD MYSQL SERVERS TO RUNTIME;

## Create ProxySQL client user

ProxySQL must have users that can access backend nodes to manage connections.

To add a user, insert credentials into mysql\_users table:

mysql@proxysql> INSERT INTO mysql\_users (username,password) VALUES ('sbuser','sbpass');

## Expected output

Query OK, 1 row affected (0.00 sec)

🧪 Note

ProxySQL currently doesn't encrypt passwords.

Load the user into runtime space and save these changes to disk (ensuring that they persist after ProxySQL shuts down):

```
mysql@proxysql> LOAD MYSQL USERS TO RUNTIME;
mysql@proxysql> SAVE MYSQL USERS TO DISK;
```

To confirm that the user has been set up correctly, you can try to log in as root:

```
root@proxysql:~# mysql -u sbuser -psbpass -h 127.0.0.1 -P 6033
```

#### Expected output

```
Welcome to the MySQL monitor. Commands end with ; or \g.
Your MySQL connection id is 1491
Server version: 5.5.30 (ProxySQL)
Copyright (c) 2009-2020 Percona LLC and/or its affiliates
Copyright (c) 2000, 2020, Oracle and/or its affiliates. All rights reserved.
Oracle is a registered trademark of Oracle Corporation and/or its
affiliates. Other names may be trademarks of their respective
owners.
Type 'help;' or '\h' for help. Type '\c' to clear the current input statement.
```

To provide read/write access to the cluster for ProxySQL, add this user on one of the Percona XtraDB Cluster nodes:

mysql@pxc3> CREATE USER 'sbuser'@'192.168.70.74' IDENTIFIED BY 'sbpass';

### Expected output

Query OK, 0 rows affected (0.01 sec)

mysql@pxc3> GRANT ALL ON \*.\* T0 'sbuser'@'192.168.70.74';

#### Expected output

Query OK, 0 rows affected (0.00 sec)

#### Test cluster with sysbench

You can install sysbench from Percona software repositories:

• For Debian or Ubuntu:

root@proxysql:~# apt install sysbench

<sup>•</sup> For Red Hat Enterprise Linux or CentOS

```
root@proxysql:~# yum install sysbench
```

🖍 Note

sysbench requires ProxySQL client user credentials that you created in Creating ProxySQL Client User.

1. Create the database that will be used for testing on one of the Percona XtraDB Cluster nodes:

mysql@pxc1> CREATE DATABASE sbtest;

2. Populate the table with data for the benchmark on the ProxySQL node:

```
root@proxysql:~# sysbench --report-interval=5 --num-threads=4 \
--num-requests=0 --max-time=20 \
--test=/usr/share/doc/sysbench/tests/db/oltp.lua \
--mysql-user='sbuser' --mysql-password='sbpass' \
--oltp-table-size=10000 --mysql-host=127.0.0.1 --mysql-port=6033 \
prepare
```

#### 3. Run the benchmark on the ProxySQL node:

```
root@proxysql:~# sysbench --report-interval=5 --num-threads=4 \
--num-requests=0 --max-time=20 \
--test=/usr/share/doc/sysbench/tests/db/oltp.lua \
--mysql-user='sbuser' --mysql-password='sbpass' \
--oltp-table-size=10000 --mysql-host=127.0.0.1 --mysql-port=6033 \
run
```

ProxySQL stores collected data in the stats schema:

mysql@proxysql> SHOW TABLES FROM stats;

For example, to see the number of commands that run on the cluster:

mysql@proxysql> SELECT \* FROM stats\_mysql\_commands\_counters;

## Expected output

Command	-	-	-		100us   cnt 500	) )us   cnt 1ms

+		+	+	+		+

## Automatic failover

ProxySQL will automatically detect if a node is not available or not synced with the cluster.

You can check the status of all available nodes by running:

mysql@proxysql> SELECT hostgroup\_id,hostname,port,status FROM runtime\_mysql\_servers;

The following output shows the status of all available nodes:

Expected outp	ut		
	+	+	
hostgroup_id	hostname	port   status	
	+	+	
0	192.168.70.71	3306   ONLINE	
	192.168.70.72		
	•	3306   ONLINE	
	•		

To test problem detection and fail-over mechanism, shut down Node 3:

root@pxc3:~# service mysql stop

ProxySQL will detect that the node is down and update its status to <code>OFFLINE\_SOFT</code> :

mysql@proxysql> SELECT hostgroup\_id,hostname,port,status FROM runtime\_mysql\_servers;

+ hostgroup_id   hostname   port   sta +	
hostgroup_id   hostname   port   sta +	
0   192.168.70.71   3306   ONL   0   192.168.70.72   3306   ONL	+
0           192.168.70.71   3306   ONL           0           192.168.70.72   3306   ONL	atus
0   192.168.70.72   3306   ONL	+
	LINE
	LINE
	FLINE_SOFT
++++++++	+
3 rows in set (0.00 sec)	

## Now start Node 3 again:

root@pxc3:~# service mysql start

The script will detect the change and mark the node as **ONLINE** :

mysql@proxysql> SELECT hostgroup\_id,hostname,port,status FROM runtime\_mysql\_servers;

Expected outp	out					
	+	++	+			
hostgroup_id	hostname	port	status			
	+	++	+			
Θ	192.168.70.71	3306	ONLINE			
Θ	192.168.70.72	3306	ONLINE			
Θ	192.168.70.73	3306	ONLINE			

## 10.8.2 Assisted maintenance mode

Usually, to take a node down for maintenance, you need to identify that node, update its status in ProxySQL to OFFLINE\_SOFT, wait for ProxySQL to divert traffic from this node, and then initiate the shutdown or perform maintenance tasks. Percona XtraDB Cluster includes a special maintenance mode for nodes that enables you to take a node down without adjusting ProxySQL manually.

Initiating pxc\_maint\_mode=MAINTENANCE does not disconnect existing connections. You must terminate these connections by either running your application code or forcing a re-connection. With a re-connection, the new connections are re-routed around the PXC node in MAINTENANCE mode.

Assisted maintenance mode is controlled via the pxc\_maint\_mode variable, which is monitored by ProxySQL and can be set to one of the following values:

- DISABLED : This value is the default state that tells ProxySQL to route traffic to the node as usual.
- SHUTDOWN : This state is set automatically when you initiate node shutdown.

You may need to shut down a node when upgrading the OS, adding resources, changing hardware parts, relocating the server, etc.

When you initiate node shutdown, Percona XtraDB Cluster does not send the signal immediately. Intead, it changes the state to pxc\_maint\_mode=SHUTDOWN and waits for a predefined period (10 seconds by default). When ProxySQL detects that the mode is set to SHUTDOWN, it changes the status of this node to OFFLINE\_SOFT. This status stops creating new node connections. After the transition period, long-running active transactions are aborted.

• MAINTENANCE: You can change to this state if you need to perform maintenance on a node without shutting it down.

You may need to isolate the node for a specific time so that it does not receive traffic from ProxySQL while you resize the buffer pool, truncate the undo log, defragment, or check disks, etc.

To do this, manually set pxc\_maint\_mode=MAINTENANCE. Control is not returned to the user for a predefined period (10 seconds by default). You can increase the transition period using the pxc\_maint\_transition\_period variable to accommodate long-running transactions. If the period is long enough for all transactions to finish, there should be little disruption in the cluster workload. If you increase the transition period, the packaging script may determine the wait as a server stall.

When ProxySQL detects that the mode is set to MAINTENANCE, it stops routing traffic to the node. During the transition period, any existing connections continue, but ProxySQL avoids opening new connections and starting transactions. Still, the user can open connections to monitor status.

Once control is returned, you can perform maintenance activity.

#### 🖍 Note

Data changes continue to be replicated across the cluster.

After you finish maintenance, set the mode back to DISABLED. When ProxySQL detects this, it starts routing traffic to the node again.

## **Related sections**

Setting up a testing environment with ProxySQL

Last update: 2023-07-21

## 10.9 ProxySQL admin utilities

The ProxySQL and ProxySQL admin utilities documentation provides information on installing and running ProxySQL 1.x.x or ProxySQL 2.x.x with the following ProxySQL admin utilities:

- The ProxySQL Admin simplifies the configuration of Percona XtraDB Cluster nodes with ProxySQL.
- The Percona Scheduler Admin tool can automatically perform a failover due to node failures, service degradation, or maintenance.

Last update: 2023-07-21

## 10.10 Set up a testing environment with ProxySQL

This section describes how to set up Percona XtraDB Cluster in a virtualized testing environment based on ProxySQL. To test the cluster, we will use the sysbench benchmark tool.

It is assumed that each PXC node is installed on Amazon EC2 micro instances running CentOS 7. However, the information in this section should apply if you used another virtualization technology (for example, VirtualBox) with any Linux distribution.

Each of the tree Percona XtraDB Cluster nodes is installed on a separate virtual machine. One more virtual machine has ProxySQL, which redirects requests to the nodes.

🖊 Тір

Running ProxySQL on an application server, instead of having it as a dedicated entity, removes the unnecessary extra network roundtrip, because the load balancing layer in Percona XtraDB Cluster scales well with application servers.

- 1. Install Percona XtraDB Cluster on three cluster nodes, as described in Configuring Percona XtraDB Cluster on CentOS.
- 2. On the client node, install ProxySQL and sysbench:

\$ yum -y install proxysql2 sysbench

3. When all cluster nodes are started, configure ProxySQL using the admin interface.

## 🧪 Tip

To connect to the ProxySQL admin interface, you need a <code>mysql</code> client. You can either connect to the admin interface from Percona XtraDB Cluster nodes that already have the <code>mysql</code> client installed (Node 1, Node 2, Node 3) or install the client on Node 4 and connect locally.

To connect to the admin interface, use the credentials, host name and port specified in the global variables.

## 🛕 Warning

Do not use default credentials in production!

The following example shows how to connect to the ProxySQL admin interface with default credentials (assuming that ProxySQL IP is 192.168.70.74):

root@proxysql:~# mysql -u admin -padmin -h 127.0.0.1 -P 6032

#### Expected output 🗡

Welcome to the MySQL monitor. Commands end with ; or \g. Your MySQL connection id is 2 Server version: 5.5.30 (ProxySQL Admin Module) Copyright (c) 2009-2020 Percona LLC and/or its affiliates Copyright (c) 2000, 2020, Oracle and/or its affiliates. All rights reserved. Oracle is a registered trademark of Oracle Corporation and/or its affiliates. Other names may be trademarks of their respective owners. Type 'help;' or '\h' for help. Type '\c' to clear the current input statement. mysql>

To see the ProxySQL databases and tables use the SHOW DATABASES and SHOW TABLES commands:

mysql> SHOW DATABASES;

The following output shows the list of the ProxySQL databases:

mysql> SHOW TABLES;

The following output shows the list of tables:

## Expected output ~

For more information about admin databases and tables, see Admin Tables

## 🖍 Note

ProxySQL has 3 areas where the configuration can reside:

- MEMORY (your current working place)
- RUNTIME (the production settings)
- DISK (durable configuration, saved inside an SQLITE database)

When you change a parameter, you change it in MEMORY area. That is done by design to allow you to test the changes before pushing to production (RUNTIME), or saving them to disk.

## Adding cluster nodes to ProxySQL

To configure the backend Percona XtraDB Cluster nodes in ProxySQL, insert corresponding records into the mysql\_servers table.

```
INSERT INTO mysql_servers (hostname,hostgroup_id,port,weight) VALUES ('192.168.70.71',10,
3306,1000);
INSERT INTO mysql_servers (hostname,hostgroup_id,port,weight) VALUES ('192.168.70.72',10,
3306,1000);
INSERT INTO mysql_servers (hostname,hostgroup_id,port,weight) VALUES ('192.168.70.73',10,
3306,1000);
```

ProxySQL v2.0 supports PXC natlively. It uses the concept of *hostgroups* (see the value of hostgroup\_id in the mysql\_servers table) to group cluster nodes to balance the load in a cluster by routing different types of traffic to different groups.

This information is stored in the [runtime\_]mysql\_galera\_hostgroups table.

Column name	Description
writer_hostgroup:	The ID of the hostgroup that refers to the WRITER node
backup_writer_hostgroup	The ID of the hostgroup that contains candidate WRITER servers
reader_hostgroup	The ID of the hostgroup that contains candidate READER servers
offline_hostgroup	The ID of the hostgroup that will eventually contain the WRITER node that will be put OFFLINE
active	1 (Yes) to inidicate that this configuration should be used; 0 (No) - otherwise
max_writers	The maximum number of WRITER nodes that must operate simultaneously. For most cases, a reasonable value is 1. The value in this column may not exceed the total number of nodes.
writer_is_also_reader	1 (Yes) to keep the given node in both reader_hostgroup and writer_hostgroup. 0 (No) to remove the given node from reader_hostgroup if it already belongs to writer_hostgroup.
max_transactions_behind	As soon as the value of :variable: <pre>wsrep_local_recv_queue</pre> exceeds the number stored in this column the given node is set to <pre>OFFLINE</pre> . Set the value carefully based on the behaviour of the node.
comment	Helpful extra information about the given node

Columns of the [runtime\_]mysql\_galera\_hostgroups table

Make sure that the variable mysql-server\_version refers to the correct version. For Percona XtraDB Cluster 8.0, set it to 8.0 accordingly:

```
mysql> UPDATE GLOBAL_VARIABLES
SET variable_value='8.0'
WHERE variable_name='mysql-server_version';
```

mysql> LOAD MYSQL SERVERS TO RUNTIME; mysql> SAVE MYSQL SERVERS TO DISK;

### 🖍 🖍 See also

Percona Blogpost: ProxySQL Native Support for Percona XtraDB Cluster (PXC) https://www.percona.com/blog/2019/02/20/proxysql-native-support-for-percona-xtradb-cluster-pxc/

Given the nodes from the mysql\_servers table, you may set up the hostgroups as follows:

```
mysql> INSERT INTO mysql_galera_hostgroups (
writer_hostgroup, backup_writer_hostgroup, reader_hostgroup,
offline_hostgroup, active, max_writers, writer_is_also_reader,
max_transactions_behind)
VALUES (10, 12, 11, 13, 1, 1, 2, 100);
```

This command configures ProxySQL as follows:

## WRITER hostgroup

hostgroup `10`

### **READER** hostgroup

hostgroup `11`

#### BACKUP WRITER hostgroup

hostgroup `12`

## **OFFLINE** hostgroup

hostgroup `13`

Set up ProxySQL query rules for read/write split using the mysql\_query\_rules table:

```
mysql> INSERT INTO mysql_query_rules (
 username,destination_hostgroup,active,match_digest,apply)
VALUES ('appuser',10,1,'^SELECT.*FOR UPDATE',1);
```

mysql> INSERT INTO mysql\_query\_rules (
username,destination\_hostgroup,active,match\_digest,apply)
VALUES ('appuser',11,1,'^SELECT ',1);

mysql> LOAD MYSQL QUERY RULES TO RUNTIME; mysql> SAVE MYSQL QUERY RULES TO DISK;

mysql> select hostgroup id,hostname,port,status,weight from runtime mysql servers;

	Expected out	put
+ -		++
	hostgroup id	hostname   port   status   weight
+-		++
	10	192.168.70.73   3306   ONLINE   1000
	11	192.168.70.72   3306   ONLINE   1000
	11	192.168.70.71   3306   ONLINE   1000
	12	192.168.70.72   3306   ONLINE   1000
	12	192.168.70.71   3306   ONLINE   1000
+ -		++
5	rows in set (	0.00 sec)

ProxySQL Blog: MySQL read/write split with ProxySQL https://proxysql.com/blog/configure-read-write-split/ ProxySQL Documentation: mysql\_query\_rules table https://github.com/sysown/proxysql/wiki/Main-(runtime)#mysql\_query\_rules

### ProxySQL failover behavior

Notice that all servers were inserted into the mysql\_servers table with the READER hostgroup set to 10 (see the value of the hostgroup\_id column):

```
mysql> SELECT * FROM mysql_servers;
```

#### Expected output

This configuration implies that ProxySQL elects the writer automatically. If the elected writer goes offline, ProxySQL assigns another (failover). You might tweak this mechanism by assigning a higher weight to a selected node. ProxySQL directs all write requests to this node. However, it also becomes the mostly utilized node for reading requests. In case of a failback (a node is put back online), the node with the highest weight is automatically elected for write requests.

#### Creating a ProxySQL monitoring user

To enable monitoring of Percona XtraDB Cluster nodes in ProxySQL, create a user with USAGE privilege on any node in the cluster and configure the user in ProxySQL.

The following example shows how to add a monitoring user on Node 2:

```
mysql> CREATE USER 'proxysql'@'%' IDENTIFIED WITH mysql_native_password BY 'ProxySQLPa55';
mysql> GRANT USAGE ON *.* TO 'proxysql'@'%';
```

The following example shows how to configure this user on the ProxySQL node:

```
mysql> UPDATE global_variables SET variable_value='proxysql'
WHERE variable_name='mysql-monitor_username';
mysql> UPDATE global_variables SET variable_value='ProxySQLPa55'
WHERE variable name='mysql-monitor password';
```

#### Saving and loading the configuration

To load this configuration at runtime, issue the LOAD command. To save these changes to disk (ensuring that they persist after ProxySQL shuts down), issue the SAVE command.

mysql> LOAD MYSQL VARIABLES TO RUNTIME; mysql> SAVE MYSQL VARIABLES TO DISK;

To ensure that monitoring is enabled, check the monitoring logs:

mysql> SELECT \* FROM monitor.mysql\_server\_connect\_log ORDER BY time\_start\_us DESC LIMIT 6;

	-
192.168.70.71   3306   1469635762434625   1695   NULL	
192.168.70.72   3306   1469635762434625   1779   NULL	
192.168.70.73   3306   1469635762434625   1627   NULL	
192.168.70.71   3306   1469635642434517   1557   NULL	
192.168.70.72   3306   1469635642434517   2737   NULL	
192.168.70.73   3306   1469635642434517   1447   NULL	

mysql> SELECT \* FROM monitor.mysql server ping log ORDER BY time start us DESC LIMIT 6;

Expected output				
+++++	-	<pre>ping success time</pre>		-
+++				•
192.168.70.71   3306	1469635762416190	948	NULL	
192.168.70.72   3306	1469635762416190	803	NULL	
192.168.70.73   3306	1469635762416190	711	NULL	
192.168.70.71   3306	1469635702416062	783	NULL	
192.168.70.72   3306	1469635702416062	631	NULL	
192.168.70.73   3306	1469635702416062	542	NULL	
+++	+	+	+	F

The previous examples show that ProxySQL is able to connect and ping the nodes you added.

To enable monitoring of these nodes, load them at runtime:

mysql> LOAD MYSQL SERVERS TO RUNTIME;

### Creating ProxySQL Client User

ProxySQL must have users that can access backend nodes to manage connections.

To add a user, insert credentials into mysql\_users table:

mysql> INSERT INTO mysql\_users (username,password) VALUES ('appuser','\$3kRetp@\$sW0rd');

The example of the output is the following:

Expected output

Query OK, 1 row affected (0.00 sec)

#### 🔪 Note

ProxySQL currently doesn't encrypt passwords.

#### See also

More information about password encryption in ProxySQL

Load the user into runtime space and save these changes to disk (ensuring that they persist after ProxySQL shuts down):

```
mysql> LOAD MYSQL USERS TO RUNTIME;
mysql> SAVE MYSQL USERS TO DISK;
```

#### To confirm that the user has been set up correctly, you can try to log in:

```
root@proxysql:~# mysql -u appuser -p$3kRetp@$sW0rd -h 127.0.0.1 -P 6033
```

#### Expected output

Welcome to the MySQL monitor. Commands end with ; or \g. Your MySQL connection id is 1491 Server version: 5.5.30 (ProxySQL)

```
Copyright (c) 2009-2020 Percona LLC and/or its affiliates
Copyright (c) 2000, 2020, Oracle and/or its affiliates. All rights reserved.
```

```
Oracle is a registered trademark of Oracle Corporation and/or its affiliates. Other names may be trademarks of their respective owners.
```

Type 'help;' or '\h' for help. Type '\c' to clear the current input statement.

To provide read/write access to the cluster for ProxySQL, add this user on one of the Percona XtraDB Cluster nodes:

mysql> CREATE USER 'appuser'@'192.168.70.74'
IDENTIFIED WITH mysql\_native\_password by '\$3kRetp@\$sW0rd';

mysql> GRANT ALL ON \*.\* TO 'appuser'@'192.168.70.74';

## 10.10.1 Testing the cluster with the sysbench benchmark tool

After you set up Percona XtraDB Cluster in your testing environment, you can test it using the sysbench benchmarking tool.

1. Create a database (sysbenchdb in this example; you can use a different name):

mysql> CREATE DATABASE sysbenchdb;

The following output confirms that a new database has been created:

## Expected output 🗡

Query OK, 1 row affected (0.01 sec)

2. Populate the table with data for the benchmark. Note that you should pass the database you have created as the value of the --mysql-db parameter, and the name of the user who has full access to this database as the value of the --mysql-user parameter:

```
$ sysbench /usr/share/sysbench/oltp_insert.lua --mysql-db=sysbenchdb \
--mysql-host=127.0.0.1 --mysql-port=6033 --mysql-user=appuser \
--mysql-password=$3kRetp@$sW0rd --db-driver=mysql --threads=10 --tables=10 \
--table-size=1000 prepare
```

## 3. Run the benchmark on port 6033:

```
$ sysbench /usr/share/sysbench/oltp_read_write.lua --mysql-db=sysbenchdb \
--mysql-host=127.0.0.1 --mysql-port=6033 --mysql-user=appuser \
--mysql-password=$3kRetp@$sW0rd --db-driver=mysql --threads=10 --tables=10 \
--skip-trx=true --table-size=1000 --time=100 --report-interval=10 run
```

# 11. Reference

## 11.1 Index of wsrep status variables

### wsrep\_apply\_oooe

This variable shows parallelization efficiency, how often writests have been applied out of order.

See also	
Galera status variable: wsrep_apply_oooe	

### wsrep\_apply\_oool

This variable shows how often a writeset with a higher sequence number was applied before one with a lower sequence number.

🖍 See also	
Galera status variable: wsrep_apply_oool	

### wsrep\_apply\_window

Average distance between highest and lowest concurrently applied sequence numbers.

🖍 See also	
Galera status variable: wsrep_apply_window	

## wsrep\_causal\_reads

Shows the number of writesets processed while the variable wsrep\_causal\_reads was set to ON.

MySQL wsrep options: wsrep\_causal\_reads

## wsrep\_cert\_bucket\_count

This variable, shows the number of cells in the certification index hash-table.

## wsrep\_cert\_deps\_distance

Average distance between highest and lowest sequence number that can be possibly applied in parallel.

Galera status variable: wsrep\_cert\_deps\_distance

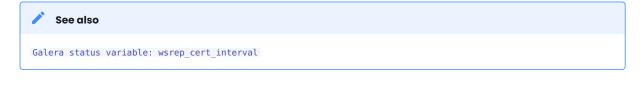

### wsrep\_cert\_index\_size

Number of entries in the certification index.

See also Galera status variable: wsrep\_cert\_index\_size

## wsrep\_cert\_interval

Average number of write-sets received while a transaction replicates.

## wsrep\_cluster\_conf\_id

Number of cluster membership changes that have taken place.

See also Galera status variable: wsrep\_cluster\_conf\_id

### wsrep\_cluster\_size

Current number of nodes in the cluster.

#### wsrep\_cluster\_state\_uuid

This variable contains UUID state of the cluster. When this value is the same as the one in wsrep\_local\_state\_uuid, node is synced with the cluster.

#### 🖍 See also

Galera status variable: wsrep\_cluster\_state\_uuid

#### wsrep\_cluster\_status

Status of the cluster component. Possible values are:

- Primary
- Non-Primary
- Disconnected

🧪 See	osic
Galera s	atus variable: wsrep_cluster_status

#### wsrep\_commit\_oooe

This variable shows how often a transaction was committed out of order.

🖍 See also	
Galera status variable: wsrep_commit_oooe	

#### wsrep\_commit\_oool

This variable currently has no meaning.

See also
Galera status variable: wsrep\_commit\_oool

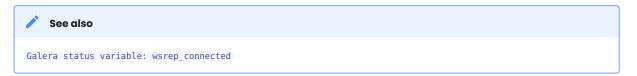

#### wsrep\_commit\_window

Average distance between highest and lowest concurrently committed sequence number.

wsrep\_connected

This variable shows if the node is connected to the cluster. If the value is OFF, the node has not yet connected to any of the cluster components. This may be due to misconfiguration.

## wsrep\_evs\_delayed

Comma separated list of nodes that are considered delayed. The node format is <uuid>:<address>:<count>, where <count> is the number of entries on delayed list for that node.

🖍 🖍 See also

Galera status variable: wsrep\_evs\_delayed

### wsrep\_evs\_evict\_list

List of UUIDs of the evicted nodes.

🖍 See also	
Galera status variable: wsrep_evs_evict_list	

## wsrep\_evs\_repl\_latency

This status variable provides information regarding group communication replication latency. This latency is measured in seconds from when a message is sent out to when a message is received.

The format of the output is <min>/<avg>/<max>/<std\_dev>/<sample\_size>.

🖍 See also	
Galera status variable: wsrep_evs_repl_latency	

## wsrep\_evs\_state

Internal EVS protocol state.

🖍 See also
Galera status variable: wsrep_evs_state

#### wsrep\_flow\_control\_interval

This variable shows the lower and upper limits for Galera flow control. The upper limit is the maximum allowed number of requests in the queue. If the queue reaches the upper limit, new requests are denied. As existing requests get processed, the queue decreases, and once it reaches the lower limit, new requests will be allowed again.

wsrep\_flow\_control\_interval\_high

Shows the upper limit for flow control to trigger.

wsrep\_flow\_control\_interval\_low

Shows the lower limit for flow control to stop.

```
wsrep_flow_control_paused
```

Time since the last status query that was paused due to flow control.

Galera status variable: wsrep\_flow\_control\_paused

### wsrep\_flow\_control\_paused\_ns

Total time spent in a paused state measured in nanoseconds.

## wsrep\_flow\_control\_recv

The number of FC\_PAUSE events received since the last status query. Unlike most status variables, this counter does not reset each time you run the query. This counter is reset when the server restarts.

🖍 See also	
Galera status variable: wsrep_flow_control_recv	

### wsrep\_flow\_control\_requested

This variable returns whether or not a node requested a replication pause.

wsrep\_flow\_control\_sent

The number of FC\_PAUSE events sent since the last status query. Unlike most status variables, this counter does not reset each time you run the query. This counter is reset when the server restarts.

#### wsrep\_flow\_control\_status

This variable shows whether a node has flow control enabled for normal traffic. It does not indicate the status of flow control during SST.

#### wsrep\_gcache\_pool\_size

This variable shows the size of the page pool and dynamic memory allocated for GCache (in bytes).

#### wsrep\_gcomm\_uuid

This status variable exposes UUIDs in gvwstate.dat, which are Galera view IDs (thus unrelated to cluster state UUIDs). This UUID is unique for each node. You will need to know this value when using manual eviction feature.

Galera status variable: wsrep\_gcomm\_uuid

#### wsrep\_incoming\_addresses

Shows the comma-separated list of incoming node addresses in the cluster.

## wsrep\_ist\_receive\_status

This variable displays the progress of IST for joiner node. If IST is not running, the value is blank. If IST is running, the value is the percentage of transfer completed.

wsrep\_ist\_receive\_seqno\_end

The sequence number of the last transaction in IST.

wsrep\_ist\_receive\_seqno\_current

The sequence number of the current transaction in IST.

wsrep\_ist\_receive\_seqno\_start

The sequence number of the first transaction in IST.

wsrep\_last\_applied

Sequence number of the last applied transaction.

wsrep\_last\_committed

Sequence number of the last committed transaction.

wsrep\_local\_bf\_aborts

Number of local transactions that were aborted by replica transactions while being executed.

#### wsrep\_local\_cached\_downto

The lowest sequence number in GCache. This information can be helpful with determining IST and SST. If the value is 0, then it means there are no writesets in GCache (usual for a single node).

Galera status variable: wsrep\_local\_cached\_downto

### wsrep\_local\_cert\_failures

Number of writesets that failed the certification test.

## wsrep\_local\_commits

Number of writesets commited on the node.

🖍 See also

Galera status variable: wsrep\_local\_commits

## wsrep\_local\_index

Node's index in the cluster.

See also Galera status variable: wsrep\_local\_index

#### wsrep\_local\_recv\_queue

Current length of the receive queue (that is, the number of writesets waiting to be applied).

#### wsrep\_local\_recv\_queue\_avg

Average length of the receive queue since the last status query. When this number is bigger than 0 this means node can't apply writesets as fast as they are received. This could be a sign that the node is overloaded and it may cause replication throttling.

#### wsrep\_local\_replays

Number of transaction replays due to asymmetric lock granularity.

## wsrep\_local\_send\_queue

Current length of the send queue (that is, the number of writesets waiting to be sent).

## wsrep\_local\_send\_queue\_avg

Average length of the send queue since the last status query. When cluster experiences network throughput issues or replication throttling, this value will be significantly bigger than 0.

See also Galera status variable: wsrep\_local\_send\_queue\_avg

## wsrep\_local\_state

Internal Galera cluster FSM state number.

🖍 See also

Galera status variable: wsrep\_local\_state

#### wsrep\_local\_state\_comment

Internal number and the corresponding human-readable comment of the node's state. Possible values are:

Num	Comment	Description
1	Joining	Node is joining the cluster
2	Donor/Desynced	Node is the donor to the node joining the cluster
3	Joined	Node has joined the cluster
4	Synced	Node is synced with the cluster

## 🖍 See also

Galera status variable: wsrep\_local\_state\_comment

#### wsrep\_local\_state\_uuid

The UUID of the state stored on the node.

🖍 See also	
Galera status variable: wsrep_local_state_uuid	

### wsrep\_monitor\_status

The status of the local monitor (local and replicating actions), apply monitor (apply actions of write-set), and commit monitor (commit actions of write sets). In the value of this variable, each monitor (L: Local, A: Apply, C: Commit) is represented as a *last\_entered*, and *last\_left* pair:

wsrep\_monitor\_status (L/A/C) [ ( 7, 5), (2, 2), ( 2, 2) ]

## last\_entered

Shows which transaction or write-set has recently entered the queue.

## last\_left

Shows which last transaction or write-set has been executed and left the queue.

According to the Galera protocol, transactions can be applied in parallel but must be committed in a given order. This rule implies that there can be multiple transactions in the *apply* state at a given point of time but transactions are *committed* sequentially.

```
See also
Galera Documentation: Database replication
```

#### wsrep\_protocol\_version

Version of the wsrep protocol used.

#### wsrep\_provider\_name

Name of the wsrep provider (usually Galera).

See also
Galera status variable: wsrep\_provider\_name

wsrep\_provider\_vendor

Name of the wsrep provider vendor (usually Codership Oy)

Galera status variable: wsrep\_provider\_vendor

### wsrep\_provider\_version

Current version of the wsrep provider.

See also Galera status variable: wsrep\_provider\_version

## wsrep\_ready

This variable shows if node is ready to accept queries. If status is 0FF, almost all queries will fail with ERROR 1047 (08501) Unknown Command error (unless the wsrep\_on variable is set to 0).

🖍 See also	
Galera status variable: wsrep_ready	

## wsrep\_received

Total number of writesets received from other nodes.

See also Galera status variable: wsrep\_received

## wsrep\_received\_bytes

Total size (in bytes) of writesets received from other nodes.

## wsrep\_repl\_data\_bytes

Total size (in bytes) of data replicated.

## wsrep\_repl\_keys

Total number of keys replicated.

wsrep\_repl\_keys\_bytes

Total size (in bytes) of keys replicated.

wsrep\_repl\_other\_bytes

Total size of other bits replicated.

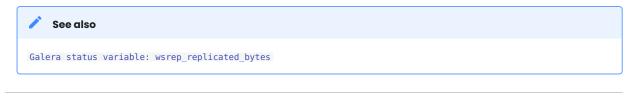

### wsrep\_replicated

Total number of writesets sent to other nodes.

🖍 See also
Galera status variable: wsrep_replicated

## wsrep\_replicated\_bytes

Total size of replicated writesets. To compute the actual size of bytes sent over network to cluster peers, multiply the value of this variable by the number of cluster peers in the given network segment.

Last update: 2023-09-11

## 11.2 Index of wsrep system variables

Percona XtraDB Cluster introduces a number of MySQL system variables related to write-set replication.

pxc\_encrypt\_cluster\_traffic

Option	Description
Command Line:	pxc-encrypt-cluster-traffic
Config File:	Yes
Scope:	Global
Dynamic:	No
Default Value:	ON

Enables automatic configuration of SSL encryption. When disabled, you need to configure SSL manually to encrypt Percona XtraDB Cluster traffic.

Possible values:

- ON, 1, true: Enabled (default)
- OFF, 0, false: Disabled

For more information, see SSL Automatic Configuration.

pxc\_maint\_mode

Option	Description
Command Line:	pxc-maint-mode
Config File:	Yes

Option	Description
Scope:	Global
Dynamic:	Yes
Default Value:	DISABLED

Specifies the maintenance mode for taking a node down without adjusting settings in ProxySQL.

The following values are available:

- DISABLED : This is the default state that tells ProxySQL to route traffic to the node as usual.
- SHUTDOWN : This state is set automatically when you initiate node shutdown.
- MAINTENANCE: You can manually change to this state if you need to perform maintenance on a node without shutting it down.

For more information, see Assisted Maintenance Mode.

pxc\_maint\_transition\_period

Option	Description
Command Line:	pxc-maint-transition-period
Config File:	Yes
Scope:	Global
Dynamic:	Yes
Default Value:	10 (ten seconds)

Defines the transition period when you change pxc\_maint\_mode to SHUTDOWN or MAINTENANCE. By default, the period is set to 10 seconds, which should be enough for most transactions to finish. You can increase the value to accommodate for longer-running transactions.

For more information, see Assisted Maintenance Mode.

	рхс	strict	mode
--	-----	--------	------

Option	Description
Command Line:	pxc-strict-mode
Config File:	Yes
Scope:	Global
Dynamic:	Yes
Default Value:	ENFORCING or DISABLED

Controls PXC Strict Mode, which runs validations to avoid the use of experimental and unsupported features in Percona XtraDB Cluster.

Depending on the actual mode you select, upon encountering a failed validation, the server will either throw an error (halting startup or denying the operation), or log a warning and continue running as normal. The following modes are available:

- DISABLED : Do not perform strict mode validations and run as normal.
- PERMISSIVE : If a validation fails, log a warning and continue running as normal.
- ENFORCING: If a validation fails during startup, halt the server and throw an error. If a validation fails during runtime, deny the operation and throw an error.
- MASTER: The same as ENFORCING except that the validation of explicit table locking is not performed. This mode can be used with clusters in which write operations are isolated to a single node.

By default, pxc\_strict\_mode is set to ENFORCING, except if the node is acting as a standalone server or the node is bootstrapping, then pxc\_strict\_mode defaults to DISABLED.

When changing the value of pxc\_strict\_mode from DISABLED or PERMISSIVE to ENFORCING or MASTER, ensure that the following configuration is used:

- wsrep\_replicate\_myisam=OFF
- binlog\_format=ROW
- log\_output=FILE **Or** log\_output=NONE **Or** log\_output=FILE,NONE

The SERIALIZABLE method of isolation is not allowed in ENFORCING mode.

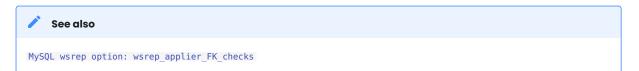

For more information, see PXC Strict Mode.

wsrep\_applier\_FK\_checks

Option	Description
Command Line:	wsrep-applier-FK-checks
Config File:	Yes
Scope:	Global
Dynamic:	Yes
Default Value:	ON

As of *Percona XtraDB Cluster* 8.0.26-16, the wsrep\_slave\_FK\_checks variable is deprecated in favor of this variable.

Defines whether foreign key checking is done for applier threads. This is enabled by default.

#### wsrep\_applier\_threads

Option	Description
Command Line:	wsrep-applier-threads
Config File:	Yes
Scope:	Global
Dynamic:	Yes
Default Value:	1

As of *Percona XtraDB Cluster* 8.0.26-16, the wsrep\_slave\_threads variable is deprecated and may be removed in a later version. Use the wsrep\_applier\_threads variable.

Specifies the number of threads that can apply replication transactions in parallel. Galera supports true parallel replication that applies transactions in parallel only when it is safe to do so. This variable is dynamic. You can increase/decrease it at any time.

When you decrease the number of threads, it won't kill the threads immediately, but stop them after they are done applying current transaction (the effect with an increase is immediate though).

If any replication consistency problems are encountered, it's recommended to set this back to 1 to see if that resolves the issue. The default value can be increased for better throughput.

You may want to increase it as suggested in Codership documentation for flow control: when the node is in JOINED state, increasing the number of replica threads can speed up the catchup to SYNCED.

You can also estimate the optimal value for this from wsrep\_cert\_deps\_distance as suggested in the Galera Cluster documentation.

For more configuration tips, see Setting Parallel Slave Threads'.

#### wsrep\_applier\_UK\_checks

Option	Description
Command Line:	wsrep-applier-UK-checks
Config File:	Yes
Scope:	Global
Dynamic:	Yes
Default Value:	OFF

As of *Percona XtraDB Cluster* 8.0.26-16, the wsrep\_slave\_UK\_checks variable is deprecated and may be removed in a later version. Use the wsrep\_applier\_UK\_checks variable.

Defines whether unique key checking is done for applier threads. This is disabled by default.

#### wsrep\_auto\_increment\_control

Option	Description
Command Line:	wsrep-auto-increment-control
Config File:	Yes
Scope:	Global
Dynamic:	Yes
Default Value:	ON

Enables automatic adjustment of auto-increment system variables depending on the size of the cluster:

- auto increment increment controls the interval between successive AUTO INCREMENT column values
- auto\_increment\_offset determines the starting point for the AUTO\_INCREMENT column value

This helps prevent auto-increment replication conflicts across the cluster by giving each node its own range of auto-increment values. It is enabled by default.

Automatic adjustment may not be desirable depending on application's use and assumptions of autoincrements. It can be disabled in source-replica clusters.

🖍 See also
MySQL wsrep option: wsrep_auto_increment_control

wsrep\_causal\_reads

Option	Description
Command Line:	wsrep-causal-reads
Config File:	Yes
Scope:	Global, Session
Dynamic:	Yes
Default Value:	OFF

In some cases, the source may apply events faster than a replica, which can cause source and replica to become out of sync for a brief moment. When this variable is set to 0N, the replica will wait until that event is applied before doing any other queries. Enabling this variable will result in larger latencies.

#### Note

This variable was deprecated because enabling it is the equivalent of setting wsrep\_sync\_wait to 1.

See also
MySQL wsrep option: wsrep_causal_reads

#### wsrep\_certification\_rules

Option	Description
Command Line:	wsrep-certification-rules
Config File:	Yes
Scope:	Global
Dynamic:	Yes
Values:	STRICT, OPTIMIZED
Default Value:	STRICT

This variable controls how certification is done in the cluster, in particular this affects how foreign keys are handled.

**STRICT** Two INSERTs that happen at about the same time on two different nodes in a child table, that insert different (non conflicting rows), but both rows point to the same row in the parent table **may result** in the certification failure.

**OPTIMIZED** Two INSERTs that happen at about the same time on two different nodes in a child table, that insert different (non conflicting rows), but both rows point to the same row in the parent table **will not result** in the certification failure.

#### wsrep\_certify\_nonPK

Option	Description
Command Line:	wsrep-certify-nonpk
Config File:	Yes
Scope:	Global
Dynamic:	No
Default Value:	ON

Enables automatic generation of primary keys for rows that don't have them. Write set replication requires primary keys on all tables to allow for parallel applying of transactions. This variable is enabled by default. As a rule, make sure that all tables have primary keys.

🖍 See also

MySQL wsrep option: wsrep\_certify\_nonPK

## wsrep\_cluster\_address

Option	Description
Command Line:	wsrep-cluster-address
Config File:	Yes
Scope:	Global
Dynamic:	Yes

Defines the back-end schema, IP addresses, ports, and options that the node uses when connecting to the cluster. This variable needs to specify at least one other node's address, which is alive and a member of the cluster. In practice, it is best (but not necessary) to provide a complete list of all possible cluster nodes. The value should be of the following format:

<schema>://<address>[?<option1>=<value1>[&<option2>=<value2>]],...

The only back-end schema currently supported is gcomm. The IP address can contain a port number after a colon. Options are specified after ? and separated by &. You can specify multiple addresses separated by commas.

#### For example:

wsrep cluster address="gcomm://192.168.0.1:4567?gmcast.listen addr=0.0.0.0:5678"

If an empty gcomm:// is provided, the node will bootstrap itself (that is, form a new cluster). It is not recommended to have empty cluster address in production config after the cluster has been bootstrapped initially. If you want to bootstrap a new cluster with a node, you should pass the --wsrep-new-cluster option when starting.

#### wsrep\_cluster\_name

Option	Description
Command Line:	wsrep-cluster-name
Config File:	Yes
Scope:	Global
Dynamic:	No
Default Value:	my_wsrep_cluster

Specifies the name of the cluster and must be identical on all nodes. A node checks the value when attempting to connect to the cluster. If the names match, the node connects.

Edit the value in the my.cnf in the [galera] section.

```
[galera]
```

wsrep cluster name=simple-cluster

Execute SHOW VARIABLES with the LIKE operator to view the variable:

```
mysql> SHOW VARIABLES LIKE 'wsrep_cluster_name';
```

## Expected output

## 🖍 Note

It should not exceed 32 characters. A node cannot join the cluster if the cluster names do not match. You must rebootstrap the cluster after a name change.

🖍 See also	
MySQL wsrep option: wsrep_cluster_name	

### wsrep\_data\_home\_dir

Option	Description
Command Line:	No
Config File:	Yes
Scope:	Global
Dynamic:	Νο
Default Value:	/var/lib/mysql (or whatever path is specified by datadir)

Specifies the path to the directory where the wsrep provider stores its files (such as grastate.dat).

#### 🖍 See also

MySQL wsrep option: wsrep\_data\_home\_dir

#### wsrep\_dbug\_option

Option	Description
Command Line:	wsrep-dbug-option
Config File:	Yes
Scope:	Global
Dynamic:	Yes

Defines DBUG options to pass to the wsrep provider.

🖍 See also
MySQL wsrep option: wsrep_dbug_option

#### wsrep\_debug

Option	Description
Command Line:	wsrep-debug
Config File:	Yes
Scope:	Global
Dynamic:	Yes
Default Value:	NONE

Enables debug level logging for the database server and <u>wsrep-lib</u> - an integration library for WSREP API with additional convenience for transaction processing. By default, --wsrep-debug variable is disabled.

This variable can be used when trying to diagnose problems or when submitting a bug.

You can set wsrep\_debug in the following my.cnf groups:

- Under [mysqld] it enables debug logging for mysqld and the SST script.
- Under [sst] it enables debug logging for the SST script only.

This variable may be set to one of the following values:

## NONE

No debug-level messages.

## SERVER

wsrep-lib general debug-level messages and detailed debug-level messages from the *server\_state* part are printed out. Galera debug-level logs are printed out.

## TRANSACTION

Same as SERVER + wsrep-lib transaction part

## STREAMING

Same as TRANSACTION + wsrep-lib streaming part

## CLIENT

Same as STREAMING + wsrep-lib client\_service part

## 🖍 Note

Do not enable debugging in production environments, because it logs authentication info (that is, passwords).

## 🖍 See also

MySQL wsrep option: wsrep\_debug

#### wsrep\_desync

Option	Description	
Command Line:	No	
Config File:	Yes	
Scope:	Global	
Dynamic:	Yes	
Default Value:	OFF	

Defines whether the node should participate in Flow Control. By default, this variable is disabled, meaning that if the receive queue becomes too big, the node engages in Flow Control: it works through the receive queue until it reaches a more manageable size. For more information, see <a href="https://wsrep\_local\_recv\_queue">wsrep\_local\_recv\_queue</a> and </a>

Enabling this variable will disable Flow Control for the node. It will continue to receive write-sets that it is not able to apply, the receive queue will keep growing, and the node will keep falling behind the cluster indefinitely.

Toggling this back to OFF will require an IST or an SST, depending on how long it was desynchronized. This is similar to cluster desynchronization, which occurs during RSU TOI. Because of this, it's not a good idea to enable wsrep\_desync for a long period of time or for several nodes at once.

You can also desync a node using the  $/\*!$  WSREP\_DESYNC \*/ query comment.

#### 🖍 See also

MySQL wsrep option: wsrep\_desync

wsrep\_dirty\_reads

Option	Description
Command Line:	wsrep-dirty-reads
Config File:	Yes

Option	Description
Scope:	Session, Global
Dynamic:	Yes
Default Value:	OFF

Defines whether the node accepts read queries when in a non-operational state, that is, when it loses connection to the Primary Component. By default, this variable is disabled and the node rejects all queries, because there is no way to tell if the data is correct.

If you enable this variable, the node will permit read queries (USE, SELECT, LOCK TABLE, and UNLOCK TABLES), but any command that modifies or updates the database on a non-operational node will still be rejected (including DDL and DML statements, such as INSERT, DELETE, and UPDATE).

To avoid deadlock errors, set the wsrep\_sync\_wait variable to 0 if you enable wsrep\_dirty\_reads.

As of Percona XtraDB Cluster 8.0.26-16, you can update the variable with a set\_var hint.

```
mysql> SELECT @@wsrep_dirty_reads;
```

## Expected output

```
+----+
| @@wsrep_dirty_reads |
+======+
| OFF |
+---++
```

mysql> SELECT /\*+ SET\_VAR(wsrep\_dirty\_reads=ON) \*/ @@wsrep\_dirty\_reads;

## Expected output

```
+----+
| @@wsrep_dirty_reads |
+======+
| ON |
+----+
```

#### 🖍 See also

MySQL wsrep option: wsrep\_dirty\_reads

#### wsrep\_drupal\_282555\_workaround

Option	Description
Command Line:	wsrep-drupal-282555-workaround
Config File:	Yes
Scope:	Global

Option	Description
Dynamic:	Yes
Default Value:	OFF

Enables a workaround for MySQL InnoDB bug that affects Drupal (Drupal bug #282555 and MySQL bug #41984). In some cases, duplicate key errors would occur when inserting the DEFAULT value into an AUTO\_INCREMENT column.

🖍 See also	
MySQL wsrep option: wsrep_drupal_282555_workaround	

#### wsrep\_forced\_binlog\_format

Option	Description
Command Line:	wsrep-forced-binlog-format
Config File:	Yes
Scope:	Global
Dynamic:	Yes
Default Value:	NONE

Defines a binary log format that will always be effective, regardless of the client session binlog\_format variable value.

Possible values for this variable are:

- ROW : Force row-based logging format
- STATEMENT : Force statement-based logging format
- MIXED : Force mixed logging format
- NONE : Do not force the binary log format and use whatever is set by the binlog\_format variable (default)

## 🖍 See also

MySQL wsrep option: wsrep\_forced\_binlog\_format

#### wsrep\_ignore\_apply\_errors

Option	Description
Command Line:	wsrep-ignore-apply-errors
Config File:	Yes
Scope:	Global
Dynamic:	Yes
Default Value:	0

Defines the rules of wsrep applier behavior on errors. You can change the settings by editing the <code>my.cnf</code> file under <code>[mysqld]</code> or at runtime.

## 🖍 Note

In Percona XtraDB Cluster version 8.0.19–10, the default value has changed from 7 to 0. If you have been working with an earlier version of the PXC 8.0 series, you may see different behavior when upgrading to this version or later.

The variable has the following options:

Value	Description
WSREP_IGNORE_ERRORS_NONE	All replication errors are treated as errors and will shutdown the node (default behavior)
WSREP_IGNORE_ERRORS_ON_RECONCILING_DDL	DROP DATABASE, DROP TABLE, DROP INDEX, ALTER TABLE are converted to a warning if they result in ER_DB_DROP_EXISTS, ER_BAD_TABLE_ERROR OR ER_CANT_DROP_FIELD_OR_KEY errors
WSREP_IGNORE_ERRORS_ON_RECONCILING_DML	DELETE events are treated as warnings if they failed because the deleted row was not found (ER_KEY_NOT_FOUND)
WSREP_IGNORE_ERRORS_ON_DDL	All DDL errors will be treated as a warning
WSREP_IGNORE_ERRORS_MAX	Infers WSREP_IGNORE_ERRORS_ON_RECONCILING_DDL, WSREP_IGNORE_ERRORS_ON_RECONCILING_DML and WSREP_IGNORE_ERRORS_ON_DDL

Setting the variable between 0 and 7 has the following behavior:

Setting	Behavior
0	WSREP_IGNORE_ERRORS_NONE
1	WSREP_IGNORE_ERRORS_ON_RECONCILING_DDL
2	WSREP_IGNORE_ERRORS_ON_RECONCILING_DML
3	WSREP_IGNORE_ERRORS_ON_RECONCILING_DDL, WSREP_IGNORE_ERRORS_ON_RECONCILING_DML
4	WSREP_IGNORE_ERRORS_ON_DDL
5	WSREP_IGNORE_ERRORS_ON_DDL, WSREP_IGNORE_ERRORS_ON_RECONCILING_DDL
6	WSREP_IGNORE_ERRORS_ON_DDL, WSREP_IGNORE_ERRORS_ON_RECONCILING_DML
7	WSREP_IGNORE_ERRORS_ON_DDL, WSREP_IGNORE_ERRORS_ON_RECONCILING_DML, WSREP_IGNORE_ERRORS_ON_RECONCILING_DDL

wsrep\_min\_log\_verbosity

Option	Description
Command Line:	wsrep-min-log-verbosity
Config File:	Yes

Option	Description
Scope:	Global
Dynamic:	Yes
Default Value:	3

This variable defines the *minimum* logging verbosity of wsrep/Galera and acts in conjunction with the log\_error\_verbosity variable. The wsrep\_min\_log\_verbosity has the same values as log\_error\_verbosity.

The actual log verbosity of wsrep/Galera can be greater than the value of wsrep\_min\_log\_verbosity if log\_error\_verbosity is greater than wsrep\_min\_log\_verbosity.

## A few examples:

log_error_verbosity	wsrep_min_log_verbosity	MySQL Logs Verbosity	wsrep Logs Verbosity
2	3	system error, warning	system error, warning, info
1	3	system error	system error, warning, info
1	2	system error	system error, warning
3	1	system error, warning, info	system error, warning, info

Note the case where log\_error\_verbosity=3 and wsrep\_min\_log\_verbosity=1. The actual log verbosity of wsrep/Galera is 3 (system error, warning, info) because log\_error\_verbosity is greater.

🖍 See also	
MySQL Documentation: log_e	error_verbosity
Galera Cluster Documentatio	n: Database Server Logs

## wsrep\_load\_data\_splitting

Option	Description
Command Line:	wsrep-load-data-splitting
Config File:	Yes
Scope:	Global
Dynamic:	Yes
Default Value:	ON

Defines whether the node should split large LOAD DATA transactions. This variable is enabled by default, meaning that LOAD DATA commands are split into transactions of 10 000 rows or less.

If you disable this variable, then huge data loads may prevent the node from completely rolling the operation back in the event of a conflict, and whatever gets committed stays committed.

#### Note

It doesn't work as expected with autocommit=0 when enabled.

🖍 See also	
MySQL wsrep option: wsrep_load_data_splitting	

#### wsrep\_log\_conflicts

Option	Description
Command Line:	wsrep-log-conflicts
Config File:	Yes
Scope:	Global
Dynamic:	No
Default Value:	OFF

Defines whether the node should log additional information about conflicts. By default, this variable is disabled and Percona XtraDB Cluster uses standard logging features in MySQL.

If you enable this variable, it will also log table and schema where the conflict occurred, as well as the actual values for keys that produced the conflict.

See also MySQL wsrep option: wsrep\_log\_conflicts

wsrep\_max\_ws\_rows

Option	Description
Command Line:	wsrep-max-ws-rows
Config File:	Yes
Scope:	Global
Dynamic:	Yes
Default Value:	0 (no limit)

Defines the maximum number of rows each write-set can contain.

By default, there is no limit for the maximum number of rows in a write-set. The maximum allowed value is 1048576.

#### 🖍 See also

MySQL wsrep option: wsrep\_max\_ws\_rows

#### wsrep\_max\_ws\_size

Option	Description
Command Line:	wsrep_max_ws_size
Config File:	Yes
Scope:	Global
Dynamic:	Yes
Default Value:	2147483647 (2 GB)

Defines the maximum write-set size (in bytes). Anything bigger than the specified value will be rejected.

You can set it to any value between 1024 and the default 2147483647.

See also
MySQL wsrep option: wsrep_max_ws_size

#### wsrep\_mode

Option	Description
Command Line:	wsrep-mode
Config File:	Yes
Scope:	Global
Dynamic:	Yes
Default Value:	

This variable has been implemented in Percona XtraDB Cluster 8.0.31.

Defines the node behavior according to a specified value. The value is empty or disabled by default.

The available values are:

- Empty does not change the node behavior.
- IGNORE\_NATIVE\_REPLICATION\_FILTER\_RULES changes the wsrep behavior to ignore native replication filter rules.

## 🖍 See also

MySQL wsrep option: wsrep\_mode

wsrep\_node\_address

Option	Description
Command Line:	wsrep-node-address
Config File:	Yes

Option	Description
Scope:	Global
Dynamic:	No
Default Value:	IP of the first network interface ( ${\tt eth0}$ ) and default port ( 4567 )

Specifies the network address of the node. By default, this variable is set to the IP address of the first network interface (usually eth0 or enp2s0) and the default port (4567).

While default value should be correct in most cases, there are situations when you need to specify it manually. For example:

- Servers with multiple network interfaces
- Servers that run multiple nodes
- Network Address Translation (NAT)
- Clusters with nodes in more than one region
- Container deployments, such as Docker
- Cloud deployments, such as Amazon EC2 (use the global DNS name instead of the local IP address)

The value should be specified in the following format:

<ip\_address>[:port]

🖍 Note

The value of this variable is also used as the default value for the wsrep\_sst\_receive\_address variable and the ist.recv\_addr option.

#### See also

MySQL wsrep option: wsrep\_node\_address

## wsrep\_node\_incoming\_address

Option	Description
Command Line:	wsrep-node-incoming-address
Config File:	Yes
Scope:	Global
Dynamic:	No
Default Value:	AUTO

Specifies the network address from which the node expects client connections. By default, it uses the IP address from wsrep node address and port number 3306.

This information is used for the wsrep\_incoming\_addresses variable which shows all active cluster nodes.

#### See also

MySQL wsrep option: wsrep\_node\_incoming\_address

#### wsrep\_node\_name

Option	Description
Command Line:	wsrep-node-name
Config File:	Yes
Scope:	Global
Dynamic:	Yes
Default Value:	The node's host name

Defines a unique name for the node. Defaults to the host name.

In many situations, you may use the value of this variable as a means to identify the given node in the cluster as the alternative to using the node address (the value of the <a href="https://www.wsrep\_node\_address">wsrep\_node\_address</a>).

#### 🧪 Note

The variable <u>wsrep\_sst\_donor</u> is an example where you may only use the value of <u>wsrep\_node\_name</u> and the node address is not permitted.

### wsrep\_notify\_cmd

Option	Description
Command Line:	wsrep-notify-cmd
Config File:	Yes
Scope:	Global
Dynamic:	No

Specifies the notification command that the node should execute whenever cluster membership or local node status changes. This can be used for alerting or to reconfigure load balancers.

The node will block and wait until the command or script completes and returns before it can proceed. If the script performs any potentially blocking or long-running operations, such as network communication, you should consider initiating such operations in the background and have the script return immediately.

MySQL wsrep option: wsrep\_notify\_cmd

wsrep\_on

Option	Description
Command Line:	No
Config File:	No
Scope:	Session
Dynamic:	Yes
Default Value:	ON

Defines if current session transaction changes for a node are replicated to the cluster.

If set to OFF for a session, no transaction changes are replicated in that session. The setting does not cause the node to leave the cluster, and the node communicates with other nodes.

🖍 See also	
MySQL wsrep option: wsrep_on	

wsrep\_OSU\_method

Option	Description
Command Line:	wsrep-OSU-method
Config File:	Yes
Scope:	Global, Session
Dynamic:	Yes
Default Value:	TOI

Defines the method for Online Schema Upgrade that the node uses to replicate DDL statements.

For information on the available methods, see Online Schema upgrade and for information on Non-blocking operations, see NBO.

wsrep\_provider

Option	Description
Command Line:	wsrep-provider
Config File:	Yes
Scope:	Global
Dynamic:	No

Specifies the path to the Galera library. This is usually /usr/lib64/libgalera\_smm.so on CentOS/RHEL and / usr/lib/libgalera\_smm.so on Debian/Ubuntu.

If you do not specify a path or the value is not valid, the node will behave as standalone instance of MySQL.

🖍 See also	
MySQL wsrep option: wsrep_provider	

#### wsrep\_provider\_options

Option	Description
Command Line:	wsrep-provider-options
Config File:	Yes
Scope:	Global
Dynamic:	No

Specifies optional settings for the replication provider documented in Index of :variable:`wsrep\_provider` options. These options affect how various situations are handled during replication.

## 🖍 See also

MySQL wsrep option: wsrep\_provider\_options

## wsrep\_recover

Option	Description
Command Line:	wsrep-recover
Config File:	Yes
Scope:	Global
Dynamic:	No
Default Value:	OFF
Location:	mysqld_safe`

Recovers database state after crash by parsing GTID from the log. If the GTID is found, it will be assigned as the initial position for server.

#### wsrep\_reject\_queries

Option	Description
Command Line:	No
Config File:	Yes
Scope:	Global

Option	Description
Dynamic:	Yes
Default Value:	NONE

Defines whether the node should reject queries from clients. Rejecting queries can be useful during upgrades, when you want to keep the node up and apply write-sets without accepting queries.

When a query is rejected, the following error is returned:

Error 1047: Unknown command

The following values are available:

- NONE : Accept all queries from clients (default)
- ALL : Reject all new queries from clients, but maintain existing client connections
- ALL\_KILL: Reject all new queries from clients and kill existing client connections

#### 🖍 Note

This variable doesn't affect Galera replication in any way, only the applications that connect to the database are affected. If you want to desync a node, use wsrep\_desync.

#### 🖍 See also

MySQL wsrep option: wsrep\_reject\_queries

#### wsrep\_replicate\_myisam

Option	Description
Command Line:	wsrep-replicate-myisam
Config File:	Yes
Scope:	Session, Global
Dynamic:	No
Default Value:	OFF

Defines whether DML statements for MyISAM tables should be replicated. It is disabled by default, because MyISAM replication is still experimental.

On the global level, wsrep\_replicate\_myisam can be set only during startup. On session level, you can change it during runtime as well.

For older nodes in the cluster, wsrep\_replicate\_myisam should work since the TOI decision (for MyISAM DDL) is done on origin node. Mixing of non-MyISAM and MyISAM tables in the same DDL statement is not recommended when wsrep\_replicate\_myisam is disabled, since if any table in the list is MyISAM, the whole DDL statement is not put under TOI.

Note

You should keep in mind the following when using MyISAM replication:

- DDL (CREATE/DROP/TRUNCATE) statements on MyISAM will be replicated irrespective of <a href="wsrep\_replicate\_myisam">wsrep\_replicate\_myisam</a> value
- DML (INSERT/UPDATE/DELETE) statements on MyISAM will be replicated only if wsrep\_replicate\_myisam is enabled
- SST will get full transfer irrespective of wsrep\_replicate\_myisam value (it will get MyISAM tables from donor)
- Difference in configuration of pxc-cluster node on enforce\_storage\_engine front may result in picking up different engine for the same table on different nodes
- CREATE TABLE AS SELECT (CTAS) statements use TOI replication. MyISAM tables are created and loaded even if wsrep\_replicate\_myisam is set to **ON**.

## wsrep\_restart\_replica

Option	Description
Command Line:	wsrep-restart-replica
Config File:	Yes
Scope:	Global
Dynamic:	Yes
Default Value:	OFF

As of *Percona XtraDB Cluster* 8.0.26-16, the wsrep\_restart\_slave variable is deprecated in favor of this variable.

Defines whether replication replica should be restarted when the node joins back to the cluster. Enabling this can be useful because asynchronous replication replica thread is stopped when the node tries to apply the next replication event while the node is in non-primary state.

🖍 See also	
MySQL wsrep option: wsrep_restart_slave	

#### wsrep\_restart\_slave

Option	Description
Command Line:	wsrep-restart-slave
Config File:	Yes
Scope:	Global
Dynamic:	Yes
Default Value:	OFF

As of *Percona XtraDB Cluster* 8.0.26-16, the wsrep\_restart\_slave variable is deprecated and may be removed in later versions. Use wsrep\_restart\_replica.

Defines whether replication replica should be restarted when the node joins back to the cluster. Enabling this can be useful because asynchronous replication replica thread is stopped when the node tries to apply the next replication event while the node is in non-primary state.

wsrep\_retry\_autocommit

Option	Description
Command Line:	wsrep-retry-autocommit
Config File:	Yes
Scope:	Global
Dynamic:	No
Default Value:	1

Specifies the number of times autocommit transactions will be retried in the cluster if it encounters certification errors. In case there is a conflict, it should be safe for the cluster node to simply retry the statement without returning an error to the client, hoping that it will pass next time.

This can be useful to help an application using autocommit to avoid deadlock errors that can be triggered by replication conflicts.

If this variable is set to 0, autocommit transactions won't be retried.

#### wsrep\_RSU\_commit\_timeout

Option	Description
Command Line:	wsrep-RSU-commit-timeout
Config File:	Yes
Scope:	Global
Dynamic:	Yes
Default Value:	5000
Range:	From 5000 (5 milliseconds) to 31536000000000 (365 days)

Specifies the timeout in microseconds to allow active connection to complete COMMIT action before starting RSU.

While running RSU it is expected that user has isolated the node and there is no active traffic executing on the node. RSU has a check to ensure this, and waits for any active connection in COMMIT state before starting RSU.

By default this check has timeout of 5 milliseconds, but in some cases COMMIT is taking longer. This variable sets the timeout, and has allowed values from the range of (5 milliseconds, 365 days). The value is to be set in microseconds. Unit of variable is in micro-secs so set accordingly.

#### Note

RSU operation will not auto-stop node from receiving active traffic. So there could be a continuous flow of active traffic while RSU continues to wait, and that can result in RSU starvation. User is expected to block active RSU traffic while performing operation.

#### wsrep\_slave\_FK\_checks

Option	Description
Command Line:	wsrep-slave-FK-checks
Config File:	Yes
Scope:	Global
Dynamic:	Yes
Default Value:	ON

As of *Percona XtraDB Cluster* 8.0.26-16, this variable is deprecated and may be removed in a later version. Use the wsrep\_applier\_FK\_checks\_variable.

Defines whether foreign key checking is done for applier threads. This is enabled by default.

#### wsrep\_slave\_threads

Option	Description
Command Line:	wsrep-slave-threads
Config File:	Yes
Scope:	Global
Dynamic:	Yes
Default Value:	1

As of *Percona XtraDB Cluster* 8.0.26-16, this variable is deprecated and may be removed in a later version. Use the wsrep\_applier\_threads variable.

Specifies the number of threads that can apply replication transactions in parallel. Galera supports true parallel replication that applies transactions in parallel only when it is safe to do so. This variable is dynamic. You can increase/decrease it at any time.

## 🧪 Note

When you decrease the number of threads, it won't kill the threads immediately, but stop them after they are done applying current transaction (the effect with an increase is immediate though).

If any replication consistency problems are encountered, it's recommended to set this back to 1 to see if that resolves the issue. The default value can be increased for better throughput.

You may want to increase it as suggested in <u>Codership documentation</u> for flow control: when the node is in JOINED state, increasing the number of replica threads can speed up the catchup to <u>SYNCED</u>.

You can also estimate the optimal value for this from wsrep\_cert\_deps\_distance as suggested in the Galera Cluster documentation.

For more configuration tips, see this document.

## wsrep\_slave\_UK\_checks

Option	Description
Command Line:	wsrep-slave-UK-checks
Config File:	Yes
Scope:	Global
Dynamic:	Yes
Default Value:	OFF

As of *Percona XtraDB Cluster* 8.0.26-16, this variable is deprecated and may be removed in a later version. Use the wsrep\_applier\_UK\_checks variable.

Defines whether unique key checking is done for applier threads. This is disabled by default.

wsrep\_SR\_store

Option	Description
Command Line:	wsrep-sr-store
Config File:	Yes
Scope:	Global
Dynamic:	No
Default Value:	table

Defines storage for streaming replication fragments. The available values are table, the default value, and none, which disables the variable.

## wsrep\_sst\_allowed\_methods

Option	Description
Command Line:	wsrep_sst_allowed_methods
Config File:	Yes
Scope:	Global
Dynamic:	No
Default Value:	xtrabackup-v2

Percona XtraDB Cluster 8.0.20-11.3 adds this variable.

This variable limits SST methods accepted by the server for  $wsrep_sst_method$  variable. The default value is xtrabackup-v2.

wsrep\_sst\_donor

Option	Description
Command Line:	Yes
Config File:	Yes
Scope:	Global
Dynamic:	Yes

Specifies a list of nodes (using their wsrep\_node\_name values) that the current node should prefer as donors for SST and IST.

#### 🛕 Warning

Using IP addresses of nodes instead of node names (the value of wsrep\_node\_name) as values of wsrep\_sst\_donor
results in an error.

ERROR] WSREP: State transfer request failed unrecoverably: 113 (No route to host). Most likely it is due to inability to communicate with the cluster primary component. Restart required.

If the value is empty, the first node in SYNCED state in the index becomes the donor and will not be able to serve requests during the state transfer.

To consider other nodes if the listed nodes are not available, add a comma at the end of the list, for example:

wsrep sst donor=node1,node2,

If you remove the trailing comma from the previous example, then the joining node will consider *only* node1 and node2.

By default, the joiner node does not wait for more than 100 seconds to receive the first packet from a donor. This is implemented via the <u>sst-initial-timeout</u> option. If you set the list of preferred donors without the trailing comma or believe that all nodes in the cluster can often be unavailable for SST (this is common for small clusters), then you may want to increase the initial timeout (or disable it completely if you don't mind the joiner node waiting for the state transfer indefinitely).

MySQL wsrep option: wsrep\_sst\_donor

wsrep\_sst\_method

Option	Description
Command Line:	wsrep-sst-method
Config File:	Yes

Option	Description
Scope:	Global
Dynamic:	Yes
Default Value:	xtrabackup-v2

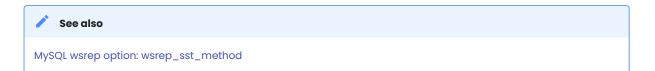

Defines the method or script for State Snapshot Transfer (SST).

Available values are:

- xtrabackup-v2: Uses *Percona XtraBackup* to perform SST. This value is the default. Privileges and permissions for running *Percona XtraBackup* can be found in Percona XtraBackup documentation. For more information, see Percona XtraBackup SST Configuration.
- skip: Use this to skip SST. **Removed in Percona XtraDB Cluster 8.0.33-25.** This value can be used when initially starting the cluster and manually restoring the same data to all nodes. This value should not be used permanently because it could lead to data inconsistency across the nodes.
- ist\_only : Introduced in Percona XtraDB Cluster 8.0.33-25. This value allows only Incremental State Transfer (IST). If a node cannot sync with the cluster with IST, abort that node's start. This action leaves the data directory unchanged. This value prevents starting a node, after a manual backup restoration, that does not have a grastate.dat file. This missing file could initiate a full-state transfer (SST) which can be a more time and resource-intensive operation.

## 🖍 Note

xtrabackup-v2 provides support for clusters with GTIDs and async replicas.

#### wsrep\_sst\_receive\_address

Option	Description
Command Line:	wsrep-sst-receive-address
Config File:	Yes
Scope:	Global
Dynamic:	Yes
Default Value:	AUTO

Specifies the network address where donor node should send state transfers. By default, this variable is set to AUTO, meaning that the IP address from wsrep\_node\_address is used.

#### See also

MySQL wsrep option: wsrep\_sst\_receive\_address

#### wsrep\_start\_position

Option	Description
Command Line:	wsrep-start-position
Config File:	Yes
Scope:	Global
Dynamic:	Yes
Default Value:	00000000-0000-0000-00000000000000000000

Specifies the node's start position as UUID: seqno. By setting all the nodes to have the same value for this variable, the cluster can be set up without the state transfer.

🖍 See also	
MySQL wsrep option: wsrep_start_position	

wsrep\_sync\_wait

Option	Description
Command Line:	wsrep-sync-wait
Config File:	Yes
Scope:	Session, Global
Dynamic:	Yes
Default Value:	Θ

Controls cluster-wide causality checks on certain statements. Checks ensure that the statement is executed on a node that is fully synced with the cluster.

As of Percona XtraDB Cluster 8.0.26-16, you are able to update the variable with a set\_var hint.

mysql> SELECT @@wsrep\_sync\_wait;

## Expected output

```
+----+
| @@wsrep_sync_wait |
+-----+
| 3 |
+----+
```

mysql> SELECT /\*+ SET\_VAR(wsrep\_sync\_wait=7) \*/ @@wsrep\_sync\_wait;

Expected output	
+	-+
<pre>@@wsrep_sync_wait</pre>	
+======================================	=+
7	
+	-+

#### 🖍 Note

Causality checks of any type can result in increased latency.

The type of statements to undergo checks is determined by bitmask:

- 0: Do not run causality checks for any statements. This is the default.
- 1: Perform checks for READ statements (including SELECT, SHOW, and BEGIN or START TRANSACTION).
- 2: Perform checks for UPDATE and DELETE statements.
- 3: Perform checks for READ, UPDATE, and DELETE statements.
- 4: Perform checks for INSERT and REPLACE statements.
- 5: Perform checks for READ, INSERT, and REPLACE statements.
- 6: Perform checks for UPDATE, DELETE, INSERT, and REPLACE statements.
- 7: Perform checks for READ, UPDATE, DELETE, INSERT, and REPLACE statements.

## 🖍 Note

Setting wsrep\_sync\_wait to 1 is the equivalent of setting the deprecated wsrep\_causal\_reads to ON.

#### 🖍 See also

MySQL wsrep option: wsrep\_sync\_wait

#### wsrep\_trx\_fragment\_size

Option	Description
Command Line:	wsrep-trx-fragment-size
Config File:	Yes
Scope:	Global, Session
Dynamic:	Yes
Default Value:	0

Defines the the streaming replication fragment size. This variable is measured in the value defined by wsrep\_trx\_fragment\_unit. The minimum value is 0 and the maximum value is 2147483647.

As of Percona XtraDB Cluster for MySQL 8.0.26-16, you can update the variable with a set\_var hint.

mysql> SELECT @@@wsrep\_trx\_fragment\_unit; SELECT @@wsrep\_trx\_fragment\_size;

```
Expected output

f @@wsrep_trx_fragment_unit |
f statements |
f @@wsrep_trx_fragment_size |
f 3 |
f ...
```

mysql> SELECT /\*+ SET\_VAR(wsrep\_trx\_fragment\_size=5) \*/ @@wsrep\_trx\_fragment\_size;

You can also use set\_var() in a data manipulation language (DML) statement. This ability is useful when streaming large statements within a transaction.

```
node1> BEGIN;
Query OK, 0 rows affected (0.00 sec)
nodel> INSERT /*+SET_VAR(wsrep_trx_fragment_size = 100)*/ INTO t1 SELECT * FROM t1;
Query OK, 65536 rows affected (15.15 sec)
Records: 65536 Duplicates: 0 Warnings: 0
node1> UPDATE /*+SET VAR(wsrep trx fragment size = 100)*/ t1 SET i=2;
Query OK, 131072 rows affected (1 min 35.93 sec)
Rows matched: 131072 Changed: 131072 Warnings: 0
node2> SET SESSION TRANSACTION ISOLATION = 'READ-UNCOMMITTED';
Query OK, 0 rows affected (0.00 sec)
node2> SELECT * FROM t1 LIMIT 5;
+--+
| i |
+===+
| 2 |
+---+
| 2 |
+--+
| 2 |
+--+
| 2 |
+--+
| 2 |
+--+
```

nodel> DELETE /\*+SET\_VAR(wsrep\_trx\_fragment\_size = 10000)\*/ FROM t1; Query OK, 131072 rows affected (15.09 sec)

#### wsrep\_trx\_fragment\_unit

Option	Description
Command Line:	wsrep-trx-fragment-unit
Config File:	Yes
Scope:	Global, Session
Dynamic:	Yes
Default Value:	"bytes"

Defines the type of measure for the wsrep\_trx\_fragment\_size. The possible values are: bytes, rows, statements.

As of Percona XtraDB Cluster for MySQL 8.0.26-16, you can update the variable with a set\_var hint.

```
mysql> SELECT @@wsrep_trx_fragment_unit; SELECT @@wsrep_trx_fragment_size;
```

# Expected output

++   @@wsrep_trx_fragment_unit   ++
statements
@@wsrep_trx_fragment_size
3 ++

mysql> SELECT /\*+ SET\_VAR(wsrep\_trx\_fragment\_unit=rows) \*/ @@wsrep\_trx\_fragment\_unit;

	+
<pre>@@wsrep_trx_fragment_unit</pre>	 ===+
rows	

Last update: 2023-08-02

## 11.3 Index of wsrep\_provider options

The following variables can be set and checked in the wsrep\_provider\_options variable. The value of the variable can be changed in the *MySQL* configuration file, my.cnf, or by setting the variable value in the *MySQL* client.

To change the value in my.cnf, the following syntax should be used:

wsrep\_provider\_options="variable1=value1;[variable2=value2]"

For example to set the size of the Galera buffer storage to 512 MB, specify the following in my.cnf:

wsrep\_provider\_options="gcache.size=512M"

Dynamic variables can be changed from the *MySQL* client using the SET GLOBAL command. For example, to change the value of the pc.ignore\_sb, use the following command:

mysql> SET GLOBAL wsrep\_provider\_options="pc.ignore\_sb=true";

## 11.3.1 Index

base\_dir

Option	Description
Command Line:	Yes
Config File:	Yes
Scope:	Global
Dynamic:	No
Default Value:	value of datadir

This variable specifies the data directory.

## base\_host

OptionDescriptionCommand Line:YesConfig File:YesScope:GlobalDynamic:NoDefault Value:value of wsrep\_node\_address

This variable sets the value of the node's base IP. This is an IP address on which Galera listens for connections from other nodes. Setting this value incorrectly would stop the node from communicating with other nodes.

base\_port

# Option Description

Command Line:	Yes
Config File:	Yes
Scope:	Global

Option	Description
Dynamic:	No
Default Value:	4567

This variable sets the port on which Galera listens for connections from other nodes. Setting this value incorrectly would stop the node from communicating with other nodes.

## cert.log\_conflicts

Option	Description
Command Line:	Yes
Config File:	Yes
Scope:	Global
Dynamic:	No
Default Value:	no

This variable is used to specify if the details of the certification failures should be logged.

## cert.optimistic\_pa

#### Enabled

Allows the full range of parallelization as determined by the certification algorithm.

## Disabled

Limits the parallel applying window so that it does not exceed the parallel applying window seen on the source. In this case, the action starts applying no sooner than all actions on the source are committed.

Option	Description
Command Line:	Yes
Config File:	Yes
Scope:	Global
Dynamic:	Yes
Default Value:	No

## 🖍 See also

Galera Cluster Documentation: \* Parameter: cert.optimistic\_pa \* Setting parallel slave threads

debug

Option	Description
Command Line:	Yes
Config File:	Yes
Scope:	Global
Dynamic:	Yes
Default Value:	no

When this variable is set to yes, it will enable debugging.

## evs.auto\_evict

Option	Description
Command Line:	Yes
Config File:	Yes
Scope:	Global
Dynamic:	Yes
Default Value:	0

Number of entries allowed on delayed list until auto eviction takes place. Setting value to 0 disables auto eviction protocol on the node, though node response times will still be monitored. EVS protocol version (evs.version) 1 is required to enable auto eviction.

evs.causal\_keepalive\_period

Option	Description
Command Line:	Yes
Config File:	Yes
Scope:	Global
Dynamic:	No
Default Value:	value of evs.keepalive_period

This variable is used for development purposes and shouldn't be used by regular users.

evs.debug\_log\_mask

Option	Description
Command Line:	Yes
Config File:	Yes
Scope:	Global
Dynamic:	Yes

Option	Description
Default Value:	0x1

This variable is used for EVS (Extended Virtual Synchrony) debugging. It can be used only when wsrep\_debug
is set to oN.

## evs.delay\_margin

Option	Description
Command Line:	Yes
Config File:	Yes
Scope:	Global
Dynamic:	Yes
Default Value:	PTIS

Time period that a node can delay its response from expected until it is added to delayed list. The value must be higher than the highest RTT between nodes.

evs.delayed\_keep\_period

Option	Description
Command Line:	Yes
Config File:	Yes
Scope:	Global
Dynamic:	Yes
Default Value:	PT30S

Time period that node is required to remain responsive until one entry is removed from delayed list.

evs.evict

Option	Description
Command Line:	Yes
Config File:	Yes
Scope:	Global
Dynamic:	Yes

Manual eviction can be triggered by setting the evs.evict to a certain node value. Setting the evs.evict to an empty string will clear the evict list on the node where it was set.

## evs.inactive\_check\_period

Option	Description
Command Line:	Yes
Config File:	Yes
Scope:	Global
Dynamic:	No
Default Value:	PT0.5S

This variable defines how often to check for peer inactivity.

## evs.inactive\_timeout

Option	Description
Command Line:	Yes
Config File:	Yes
Scope:	Global
Dynamic:	No
Default Value:	PT15S

This variable defines the inactivity limit, once this limit is reached the node will be considered dead.

evs.info\_log\_mask

Option	Description
Command Line:	Yes
Config File:	Yes
Scope:	Global
Dynamic:	No
Default Value:	0

This variable is used for controlling the extra EVS info logging.

## evs.install\_timeout

Option	Description
Command Line:	Yes
Config File:	Yes
Scope:	Global
Dynamic:	Yes
Default Value:	PT7.5S

This variable defines the timeout on waiting for install message acknowledgments.

evs.join\_retrans\_period

Option	Description
Command Line:	Yes
Config File:	Yes
Scope:	Global
Dynamic:	No
Default Value:	PTIS

This variable defines how often to retransmit EVS join messages when forming cluster membership.

evs.keepalive\_period

Option	Description
Command Line:	Yes
Config File:	Yes
Scope:	Global
Dynamic:	No
Default Value:	PTIS

This variable defines how often to emit keepalive beacons (in the absence of any other traffic).

## evs.max\_install\_timeouts

Option	Description
Command Line:	Yes
Config File:	Yes
Scope:	Global
Dynamic:	No
Default Value:	1

This variable defines how many membership install rounds to try before giving up (total rounds will be evs.max\_install\_timeouts + 2).

#### evs.send\_window

Option	Description
Command Line:	Yes
Config File:	Yes
Scope:	Global

Option	Description
Dynamic:	No
Default Value:	10

This variable defines the maximum number of data packets in replication at a time. For WAN setups, the variable can be set to a considerably higher value than default (for example,512). The value must not be less than evs.user\_send\_window.

#### evs.stats\_report\_period

Option	Description
Command Line:	Yes
Config File:	Yes
Scope:	Global
Dynamic:	No
Default Value:	PTIM

This variable defines the control period of EVS statistics reporting.

## evs.suspect\_timeout

Option	Description
Command Line:	Yes
Config File:	Yes
Scope:	Global
Dynamic:	No
Default Value:	PT5S

This variable defines the inactivity period after which the node is "suspected" to be dead. If all remaining nodes agree on that, the node will be dropped out of cluster even before <code>evs.inactive\_timeout</code> is reached.

evs.use\_aggregate

Option	Description
Command Line:	Yes
Config File:	Yes
Scope:	Global
Dynamic:	No
Default Value:	true

When this variable is enabled, smaller packets will be aggregated into one.

#### evs.user\_send\_window

Option	Description
Command Line:	Yes
Config File:	Yes
Scope:	Global
Dynamic:	Yes
Default Value:	4

This variable defines the maximum number of data packets in replication at a time. For WAN setups, the variable can be set to a considerably higher value than default (for example, 512).

## evs.version

Option	Description
Command Line:	Yes
Config File:	Yes
Scope:	Global
Dynamic:	No
Default Value:	0

This variable defines the EVS protocol version. Auto eviction is enabled when this variable is set to 1. Default 0 is set for backwards compatibility.

evs.view\_forget\_timeout

Option	Description
Command Line:	Yes
Config File:	Yes
Scope:	Global
Dynamic:	No
Default Value:	PID

This variable defines the timeout after which past views will be dropped from history.

gcache.dir

Option	Description
Command Line:	Yes
Config File:	Yes
Scope:	Global
Dynamic:	No

Option	Description
Default Value:	datadir

This variable can be used to define the location of the galera.cache file.

#### gcache.freeze\_purge\_at\_seqno

Option	Description
Command Line:	Yes
Config File:	Yes
Scope:	Local, Global
Dynamic:	Yes
Default Value:	0

This variable controls the purging of the gcache and enables retaining more data in it. This variable makes it possible to use IST (Incremental State Transfer) when the node rejoins instead of SST (State Snapshot Transfer).

Set this variable on an existing node of the cluster (that will continue to be part of the cluster and can act as a potential donor node). This node continues to retain the write-sets and allows restarting the node to rejoin by using IST.

The gcache.freeze\_purge\_at\_seqno variable takes three values:

## -1 (default)

No freezing of gcache, the purge operates as normal.

## A valid seqno in gcache

The freeze purge of write-sets may not be smaller than the selected seqno. The best way to select an optimal value is to use the value of the variable: wsrep\_last\_applied from the node that you plan to shut down.

**now** The freeze purge of write-sets is no less than the smallest seqno currently in gcache. Using this value results in freezing the gcache-purge instantly. Use this value if selecting a valid seqno in gcache is difficult.

gcache.keep\_pages\_count

 Option
 Description

 Command Line:
 Yes

 Config File:
 Yes

Option	Description
Scope:	Local, Global
Dynamic:	Yes
Default Value:	0

This variable is used to limit the number of overflow pages rather than the total memory occupied by all overflow pages. Whenever gcache.keep\_pages\_count is set to a non-zero value, excess overflow pages will be deleted (starting from the oldest to the newest).

Whenever either the gcache.keep\_pages\_count or the gcache.keep\_pages\_size variable is updated at runtime to a non-zero value, cleanup is called on excess overflow pages to delete them.

gcache.keep\_pages\_size

Option	Description
Command Line:	Yes
Config File:	Yes
Scope:	Local, Global
Dynamic:	No
Default Value:	0

This variable is used to limit the total size of overflow pages rather than the count of all overflow pages. Whenever gcache.keep\_pages\_size is set to a non-zero value, excess overflow pages will be deleted (starting from the oldest to the newest) until the total size is below the specified value.

Whenever either the gcache.keep\_pages\_count or the gcache.keep\_pages\_size variable is updated at runtime to a non-zero value, cleanup is called on excess overflow pages to delete them.

gcache.mem\_size

Option	Description
Command Line:	Yes
Config File:	Yes
Scope:	Global
Dynamic:	No
Default Value:	0

This variable has been deprecated in 5.6.22-25.8 and shouldn't be used as it could cause a node to crash.

This variable was used to define how much RAM is available for the system.

gcache.name

Option	Description
Command Line:	Yes

Option	Description
Config File:	Yes
Scope:	Global
Dynamic:	No
Default Value:	/var/lib/mysql/galera.cache

This variable can be used to specify the name of the Galera cache file.

gcache.page\_size

Option	Description
Command Line:	No
Config File:	Yes
Scope:	Global
Dynamic:	No
Default Value:	128M

Size of the page files in page storage. The limit on overall page storage is the size of the disk. Pages are prefixed by gcache.page.

#### 🖍 See also

Galera Documentation: gcache.page\_size

• Percona Database Performance Blog: All You Need to Know About GCache

gcache.recover

Option	Description
Command line:	No
Configuration file:	Yes
Scope:	Global
Dynamic:	No
Default value:	No

Attempts to recover a node's gcache file to a usable state on startup. If the node can successfully recover the gcache file, the node can provide IST to the remaining nodes. This ability can reduce the time needed to bring up the cluster.

An example of enabling the variable in the configuration file:

```
wsrep_provider_options="gcache.recover=yes"
```

gcache.size

Option	Description
Command Line:	Yes
Config File:	Yes
Scope:	Global
Dynamic:	No
Default Value:	128M

Size of the transaction cache for Galera replication. This defines the size of the galera.cache file which is used as source for IST. The bigger the value of this variable, the better are chances that the re-joining node will get IST instead of SST.

#### gcomm.thread\_prio

Using this option, you can raise the priority of the gcomm thread to a higher level than it normally uses.

The format for this variable is: <policy>:<priority>. The priority value is an integer.

#### other

```
Default time-sharing scheduling in Linux. The threads can run until blocked by an I/O request or preempted by higher priorities or superior scheduling designations.
```

## fifo

```
First-in First-out (FIFO) scheduling. These threads always immediately preempt any currently running other, batch or idle threads. They can run until they are either blocked by an I/O request or preempted by a FIFO thread of a higher priority.
```

## rr

Round-robin scheduling. These threads always preempt any currently running other, batch or idle threads. The scheduler allows these threads to run for a fixed period of a time. If the thread is still running when this time period is exceeded, they are stopped and moved to the end of the list, allowing another round-robin thread of the same priority to run in their place. They can otherwise continue to run until they are blocked by an I/O request or are preempted by threads of a higher priority.

## gcs.fc\_auto\_evict\_threshold

Option	Description
Command Line:	Yes

Option	Description
Config file :	Yes
Scope:	Global
Dynamic:	No
Default value:	0.75

Implemented in Percona XtraDB Cluster 8.0.33-25.

Defines the threshold that must be reached or crossed before a node is evicted from the cluster. This variable is a ratio of the gcs.fc\_auto\_evict\_window variable. The default value is .075, but the value can be set to any value between 0.0 and 1.0.

gcs.fc\_auto\_evict\_window

Option	Description
Command Line:	Yes
Config file :	Yes
Scope:	Global
Dynamic:	No
Default value:	0

Implemented in Percona XtraDB Cluster 8.0.33-25.

The variable defines the time window width within which flow controls are observed. The time span of the window is [now - gcs.fc\_audot\_evict\_window, now]. The window is constantly moving ahead as the time passes. And now, within this window if the flow control summary time  $\geq$  (gcs.fc\_audot-evict\_window \* gcs.fc\_audot\_evict\_threshold), the node self-leaves the cluster.

The default value is 0, which means that the feature is disabled.

The maximum value is DBL\_MAX.

gcs.fc\_debug

Option	Description
Command Line:	Yes
Config File:	Yes
Scope:	Global
Dynamic:	No
Default Value:	0

This variable specifies after how many writesets the debug statistics about SST flow control will be posted.

gcs.fc\_factor

Option	Description
Command Line:	Yes
Config File:	Yes
Scope:	Global
Dynamic:	Yes
Default Value:	1

This variable is used for replication flow control. Replication is resumed when the replica queue drops below gcs.fc\_factor \* gcs.fc\_limit.

gcs.fc\_limit

Option	Description
Command Line:	Yes
Config File:	Yes
Scope:	Global
Dynamic:	Yes
Default Value:	100

This variable is used for replication flow control. Replication is paused when the replica queue exceeds this limit. In the default operation mode, flow control limit is dynamically recalculated based on the amount of nodes in the cluster, but this recalculation can be turned off with use of the gcs.fc\_master\_slave variable to make manual setting of the gcs.fc\_limit having an effect (e.g., for configurations when writing is done to a single node in Percona XtraDB Cluster).

gcs.fc\_master\_slave

Option	Description
Command Line:	Yes
Config File:	Yes
Scope:	Global
Dynamic:	NO
Default Value:	NO

This variable is used to specify if there is only one source node in the cluster. It affects whether flow control limit is recalculated dynamically (when NO) or not (when YES).

gcs.max\_packet\_size

Option	Description
Command Line:	Yes

Option	Description
Config File:	Yes
Scope:	Global
Dynamic:	No
Default Value:	64500

This variable is used to specify the writeset size after which they will be fragmented.

gcs.max\_throttle

Option	Description
Command Line:	Yes
Config File:	Yes
Scope:	Global
Dynamic:	No
Default Value:	0.25

This variable specifies how much the replication can be throttled during the state transfer in order to avoid running out of memory. Value can be set to 0.0 if stopping replication is acceptable in order to finish state transfer.

gcs.recv\_q\_hard\_limit

Option	Description
Command Line:	Yes
Config File:	Yes
Scope:	Global
Dynamic:	No
Default Value:	9223372036854775807

This variable specifies the maximum allowed size of the receive queue. This should normally be (RAM + swap) / 2. If this limit is exceeded, Galera will abort the server.

# gcs.recv\_q\_soft\_limit

Option	Description
Command Line:	Yes
Config File:	Yes
Scope:	Global
Dynamic:	No
Default Value:	0.25

This variable specifies the fraction of the gcs.recv\_q\_hard\_limit after which replication rate will be throttled.

gcs.sync\_donor

Option	Description
Command Line:	Yes
Config File:	Yes
Scope:	Global
Dynamic:	No
Default Value:	No

This variable controls if the rest of the cluster should be in sync with the donor node. When this variable is set to YES, the whole cluster will be blocked if the donor node is blocked with SST.

gmcast.listen\_addr

Option	Description
Command Line:	Yes
Config File:	Yes
Scope:	Global
Dynamic:	No
Default Value:	tcp://0.0.0.0:4567

This variable defines the address on which the node listens to connections from other nodes in the cluster.

gmcast.mcast\_addr

Option	Description
Command Line:	Yes
Config File:	Yes
Scope:	Global
Dynamic:	No
Default Value:	None

This variable should be set up if UDP multicast should be used for replication.

gmcast.mcast\_ttl

Option	Description
Command Line:	Yes
Config File:	Yes
Scope:	Global

Option	Description
Dynamic:	No
Default Value:	1

This variable can be used to define TTL for multicast packets.

#### gmcast.peer\_timeout

Option	Description
Command Line:	Yes
Config File:	Yes
Scope:	Global
Dynamic:	No
Default Value:	PT3S

This variable specifies the connection timeout to initiate message relaying.

gmcast.segment

Option	Description
Command Line:	Yes
Config File:	Yes
Scope:	Global
Dynamic:	No
Default Value:	0

This variable specifies the group segment this member should be a part of. Same segment members are treated as equally physically close.

gmcast.time\_wait

Option	Description
Command Line:	Yes
Config File:	Yes
Scope:	Global
Dynamic:	No
Default Value:	PT5S

This variable specifies the time to wait until allowing peer declared outside of stable view to reconnect.

#### gmcast.version

Option	Description
Command Line:	Yes
Config File:	Yes
Scope:	Global
Dynamic:	No
Default Value:	0

This variable shows which gmcast protocol version is being used.

# ist.recv\_addr

Option	Description
Command Line:	Yes
Config File:	Yes
Scope:	Global
Dynamic:	No
Default Value:	value of wsrep_node_address

This variable specifies the address on which the node listens for Incremental State Transfer (IST).

## pc.announce\_timeout

Option	Description
Command Line:	Yes
Config File:	Yes
Scope:	Global
Dynamic:	No
Default Value:	PT3S

Cluster joining announcements are sent every  $\frac{1}{2}$  second for this period of time or less if other nodes are discovered.

pc.checksum

Option	Description
Command Line:	Yes
Config File:	Yes
Scope:	Global
Dynamic:	No

Option	Description
Default Value:	true

This variable controls whether replicated messages should be checksummed or not.

#### pc.ignore\_quorum

Option	Description
Command Line:	Yes
Config File:	Yes
Scope:	Global
Dynamic:	No
Default Value:	false

When this variable is set to TRUE, the node will completely ignore quorum calculations. This should be used with extreme caution even in source-replica setups, because replicas won't automatically reconnect to source in this case.

# pc.ignore\_sb

Option	Description
Command Line:	Yes
Config File:	Yes
Scope:	Global
Dynamic:	Yes
Default Value:	false

When this variable is set to TRUE, the node will process updates even in the case of a split brain. This should be used with extreme caution in multi-source setup, but should simplify things in source-replica cluster (especially if only 2 nodes are used).

# pc.linger

Option	Description
Command Line:	Yes
Config File:	Yes
Scope:	Global
Dynamic:	No
Default Value:	PT20S

This variable specifies the period for which the PC protocol waits for EVS termination.

pc.npvo

Option	Description
Command Line:	Yes
Config File:	Yes
Scope:	Global
Dynamic:	No
Default Value:	false

When this variable is set to TRUE, more recent primary components override older ones in case of conflicting primaries.

pc.recovery

Option	Description
Command Line:	Yes
Config File:	Yes
Scope:	Global
Dynamic:	No
Default Value:	true

When this variable is set to true, the node stores the Primary Component state to disk. The Primary Component can then recover automatically when all nodes that were part of the last saved state reestablish communication with each other. This feature allows automatic recovery from full cluster crashes, such as in the case of a data center power outage. A subsequent graceful full cluster restart will require explicit bootstrapping for a new Primary Component.

pc.version

Option	Description
Command Line:	Yes
Config File:	Yes
Scope:	Global
Dynamic:	No
Default Value:	0

This status variable is used to check which PC protocol version is used.

pc.wait\_prim

Option	Description
Command Line:	Yes
Config File:	Yes

Option	Description
Scope:	Global
Dynamic:	No
Default Value:	true

When set to TRUE, the node waits for a primary component for the period of time specified in pc.wait\_prim\_timeout. This is useful to bring up a non-primary component and make it primary with pc.bootstrap.

pc.wait\_prim\_timeout

Option	Description
Command Line:	Yes
Config File:	Yes
Scope:	Global
Dynamic:	No
Default Value:	PT30S

This variable is used to specify the period of time to wait for a primary component.

pc.wait\_restored\_prim\_timeout

# Introduced in Percona XtraDB Cluster 8.0.33-25.

Option	Description
Command Line:	Yes
Config File:	Yes
Scope:	Global
Dynamic	No
Default Value:	PTOS

This variable specifies the wait period for a primary component when the cluster restores the primary component from the gwstate.dat file after an outage.

The default value is PTOS (zero seconds). The node waits for an infinite time, which is the current behavior.

You can define a wait time with PTNS, replace the N value with the number of seconds. For example, to wait for 90 seconds, set the value to PT90S.

pc.weight

Option

Description

Command Line:	Yes
Config File:	Yes

Option	Description
Scope:	Global
Dynamic:	Yes
Default Value:	1

This variable specifies the node weight that's going to be used for Weighted Quorum calculations.

### protonet.backend

Option	Description
Command Line:	Yes
Config File:	Yes
Scope:	Global
Dynamic:	No
Default Value:	asio

This variable is used to define which transport backend should be used. Currently only ASI0 is supported.

protonet.version

Option	Description
Command Line:	Yes
Config File:	Yes
Scope:	Global
Dynamic:	No
Default Value:	0

This status variable is used to check which transport backend protocol version is used.

repl.causal\_read\_timeout

Option	Description
Command Line:	Yes
Config File:	Yes
Scope:	Global
Dynamic:	Yes
Default Value:	PT30S

This variable specifies the causal read timeout.

repl.commit\_order

Option	Description
Command Line:	Yes
Config File:	Yes
Scope:	Global
Dynamic:	No
Default Value:	3

This variable is used to specify out-of-order committing (which is used to improve parallel applying performance). The following values are available:

- 0 BYPASS: all commit order monitoring is turned off (useful for measuring performance penalty)
- 1 OOOC: allow out-of-order committing for all transactions
- 2 LOCAL\_OOOC: allow out-of-order committing only for local transactions
- 3 NO\_OOOC: no out-of-order committing is allowed (strict total order committing)

repl.key\_format

Option	Description
Command Line:	Yes
Config File:	Yes
Scope:	Global
Dynamic:	Yes
Default Value:	FLAT8

This variable is used to specify the replication key format. The following values are available:

- FLAT8 short key with higher probability of key match false positives
- FLAT16 longer key with lower probability of false positives
- FLAT8A same as FLAT8 but with annotations for debug purposes
- FLAT16A same as FLAT16 but with annotations for debug purposes

#### repl.max\_ws\_size

Option	Description
Command Line:	Yes
Config File:	Yes
Scope:	Global
Dynamic:	No
Default Value:	2147483647

This variable is used to specify the maximum size of a write-set in bytes. This is limited to 2 gygabytes.

repl.proto\_max

Option	Description
Command Line:	Yes
Config File:	Yes
Scope:	Global
Dynamic:	No
Default Value:	7

This variable is used to specify the highest communication protocol version to accept in the cluster. Used only for debugging.

socket.checksum

Option	Description
Command Line:	Yes
Config File:	Yes
Scope:	Global
Dynamic:	No
Default Value:	2

This variable is used to choose the checksum algorithm for network packets. The CRC32-C option is optimized and may be hardware accelerated on Intel CPUs. The following values are available:

- 0 disable checksum
- 1 plain CRC32 (used in Galera 2.x)
- 2 hardware accelerated CRC32-C

The following is an example of the variable use:

wsrep\_provider\_options="socket.checksum=2"

socket.ssl

Option	Description
Command Line:	Yes
Config File:	Yes
Scope:	Global
Dynamic:	No
Default Value:	No

This variable is used to specify if SSL encryption should be used.

socket.ssl\_ca

Option	Description
Command Line:	Yes
Config File:	Yes
Scope:	Global
Dynamic:	No

This variable is used to specify the path to the Certificate Authority (CA) certificate file.

socket.ssl\_cert

Option	Description
Command Line:	Yes
Config File:	Yes
Scope:	Global
Dynamic:	No

This variable is used to specify the path to the server's certificate file (in PEM format).

socket.ssl\_key

Option	Description
Command Line:	Yes
Config File:	Yes
Scope:	Global
Dynamic:	No

This variable is used to specify the path to the server's private key file (in PEM format).

socket.ssl\_compression

Option	Description
Command Line:	Yes
Config File:	Yes
Scope:	Global
Dynamic:	No
Default Value:	Yes

This variable is used to specify if the SSL compression is to be used.

socket.ssl\_cipher

Option	Description
Command Line:	Yes
Config File:	Yes
Scope:	Global
Dynamic:	No
Default Value:	AES128-SHA

This variable is used to specify what cypher will be used for encryption.

Last update: 2023-08-02

# 11.4 Index of files created by PXC

#### • GRA\_\\*.log

These files contain binlog events in ROW format representing the failed transaction. That means that the replica thread was not able to apply one of the transactions. For each of those file, a corresponding warning or error message is present in the mysql error log file. Those error can also be false positives like a bad DDL statement (dropping a table that doesn't exists for example) and therefore nothing to worry about. However it's always recommended to check these log to understand what's is happening.

To be able to analyze these files binlog header needs to be added to the log file. To create the GRA\_HEADER file you need an instance running with binlog\_checksum set to NONE and extract first 120 bytes from the binlog file:

```
$ head -c 123 mysqld-bin.000001 > GRA_HEADER
$ cat GRA HEADER > /var/lib/mysql/GRA 1 2-bin.log
$ cat /var/lib/mysql/GRA 1 2.log >> /var/lib/mysql/GRA 1 2-bin.log
$ mysqlbinlog -vvv /var/lib/mysql/GRA_1_2-bin.log
/*!50530 SET @@SESSION.PSEUDO SLAVE MODE=1*/;
/*!50003 SET @OLD COMPLETION TYPE=@@COMPLETION TYPE,COMPLETION TYPE=0*/;

End of log file
/*!50003 SET COMPLETION_TYPE=@OLD_COMPLETION_TYPE*/;
/*!50530 SET @@SESSION.PSEUDO SLAVE MODE=0*/;
```

This information can be used for checking the MySQL error log for the corresponding error message.

#### 📒 Error message 🗡

```
160805 9:33:37 8:52:21 [ERROR] Slave SQL: Error 'Unknown table 'test'' on query. Default
database: 'test'. Query: 'drop table test', Error_code: 1051
160805 9:33:37 8:52:21 [Warning] WSREP: RBR event 1 Query apply warning: 1, 3
```

In this example DROP TABLE statement was executed on a table that doesn't exist.

gcache.page

See gcache.page\_size

```
🖍 🖍 See also
```

Percona Database Performance Blog: All You Need to Know About GCache (Galera-Cache) https:// www.percona.com/blog/2016/11/16/all-you-need-to-know-about-gcache-galera-cache/

• galera.cache

This file is used as a main writeset store. It's implemented as a permanent ring-buffer file that is preallocated on disk when the node is initialized. File size can be controlled with the variable gcache.size. If this value is bigger, more writesets are cached and chances are better that the re-joining node will get IST instead of SST. Filename can be changed with the gcache.name variable.

grastate.dat

This file contains the Galera state information.

- version grastate version
- uuid a unique identifier for the state and the sequence of changes it undergoes. For more information on how UUID is generated see UUID.
- seqno Ordinal Sequence Number, a 64-bit signed integer used to denote the position of the change in the sequence. seqno is 0 when no writesets have been generated or applied on that node, i.e., not applied/generated across the lifetime of a grastate file. -1 is a special value for the seqno that is kept in the grastate.dat while the server is running to allow Galera to distinguish between a clean and an unclean shutdown. Upon a clean shutdown, the correct seqno value is written to the file. So, when the server is brought back up, if the value is still -1, this means that the server did not shut down cleanly. If the value is greater than 0, this means that the shutdown was clean. -1 is then written again to the file in order to allow the server to correctly detect if the next shutdown was clean in the same manner.
- cert\_index cert index restore through grastate is not implemented yet

Examples of this file look like this:

In case server node has this state when not running it means that that node crashed during the transaction processing.

```
GALERA saved state
version: 2.1
uuid: 1917033b-7081-11e2-0800-707f5d3b106b
seqno: -1
cert_index:
```

In case server node has this state when not running it means that the node was gracefully shut down.

```
GALERA saved state
version: 2.1
uuid: 1917033b-7081-11e2-0800-707f5d3b106b
seqno: 5192193423942
cert_index:
```

In case server node has this state when not running it means that the node crashed during the DDL.

```
GALERA saved state
version: 2.1
uuid: 00000000-0000-0000-0000-00000000000
seqno: -1
cert_index:
```

• gvwstate.dat

This file is used for Primary Component recovery feature. This file is created once primary component is formed or changed, so you can get the latest primary component this node was in. And this file is deleted when the node is shutdown gracefully.

First part contains the node UUID information. Second part contains the view information. View information is written between #vwbeg and #vwend. View information consists of:

```
* view id: [view type] [view uuid] [view seq]. - `view type` is always `3` which means
primary view. `view_uuid` and `view_seq` identifies a unique view, which could be perceived
as identifier of this primary component.
* bootstrap: [bootstarp_or_not]. - it could be `0` or `1`, but it does not affect primary
component recovery process now.
* member: [node's uuid] [node's segment]. - it represents all nodes in this primary
component.
??? example "Example of the file"
    ```{.text .no-copy}
   my_uuid: c5d5d990-30ee-11e4-aab1-46d0ed84b408
   #vwbea
   view id: 3 bc85bd53-31ac-11e4-9895-1f2ce13f2542 2
   bootstrap: 0
   member: bc85bd53-31ac-11e4-9895-1f2ce13f2542 0
   member: c5d5d990-30ee-11e4-aab1-46d0ed84b408 0
   #vwend
```

11.5 Telemetry on Percona XtraDB Cluster

Percona telemetry fills in the gaps in our understanding of how you use Percona XtraDB Cluster to improve our products. Participation in the anonymous program is optional. You can opt-out if you prefer to not share this information.

11.5.1 What information is collected

At this time, telemetry is added only to the Percona packages and Docker images. Percona XtraDB Cluster collects only information about the installation environment. Future releases may add additional metrics.

Be assured that access to this raw data is rigorously controlled. Percona does not collect personal data. All data is anonymous and cannot be traced to a specific user. To learn more about our privacy practices, read our Percona Privacy statement.

An example of the data collected is the following:

```
[{"id" : "c416c3ee-48cd-471c-9733-37c2886f8231",
"product_family" : "PRODUCT_FAMILY_PXC",
"instanceId" : "6aef422e-56a7-4530-af9d-94cc02198343",
"createTime" : "2023-10-16T10:46:23Z",
"metrics":
[{"key" : "deployment","value" : "PACKAGE"},
{"key" : "pillar_version","value" : "8.0.34-26"},
{"key" : "0S","value" : "0racle Linux Server 8.8"},
{"key" : "hardware_arch","value" : "x86_64 x86_64"}]}]
```

11.5.2 Disable telemetry

Starting with Percona XtraDB Cluster 8.0.34-26-1, telemetry is enabled by default. If you decide not to send usage data to Percona, you can set the PERCONA_TELEMETRY_DISABLE=1 environment variable for either the root user or in the operating system prior to the installation process.

Debian-derived distribution Red Hat-derived distribution DOCKER

Add the environment variable before the install process.

\$ sudo PERCONA TELEMETRY DISABLE=1 apt install percona-xtradb-cluster

Add the environment variable before the install process.

\$ sudo PERCONA TELEMETRY DISABLE=1 yum install percona-xtradb-cluster

Add the environment variable when running a command in a new container.

\$ docker run -d -e MYSQL_ROOT_PASSWORD=test1234# -e PERCONA_TELEMETRY_DISABLE=1 -e
CLUSTER NAME=pxc-cluster1 --name=pxc-node1 percona/percona-xtradb-cluster:8.0

```
Last update: 2023-11-01
```

11.6 Frequently asked questions

11.6.1 How do I report bugs?

All bugs can be reported on JIRA. Please submit error.log files from **all** the nodes.

11.6.2 How do I solve locking issues like auto-increment?

For auto-increment, Percona XtraDB Cluster changes auto_increment_offset for each new node. In a singlenode workload, locking is handled in the same way as *InnoDB*. In case of write load on several nodes, Percona XtraDB Cluster uses optimistic locking and the application may receive lock error in response to COMMIT query.

11.6.3 What if a node crashes and InnoDB recovery rolls back some transactions?

When a node crashes, after restarting, it will copy the whole dataset from another node (if there were changes to data since the crash).

11.6.4 How can I check the Galera node health?

To check the health of a Galera node, use the following query:

```
SELECT 1 FROM dual;
```

The following results of the previous query are possible:

- You get the row with id=1 (node is healthy)
- Unknown error (node is online, but Galera is not connected/synced with the cluster)
- Connection error (node is not online)

You can also check a node's health with the clustercheck script. First set up the clustercheck user:

```
mysql> CREATE USER 'clustercheck'@'localhost' IDENTIFIED BY PASSWORD
'*2470C0C06DEE42FD1618BB99005ADCA2EC9D1E19';
```

Expected output

Query OK, 0 rows affected (0.00 sec)

mysql> GRANT PROCESS ON *.* TO 'clustercheck'@'localhost';

You can then check a node's health by running the clustercheck script:

```
/usr/bin/clustercheck clustercheck password 0
```

If the node is running, you should get the following status:

```
HTTP/1.1 200 OK
Content-Type: text/plain
Connection: close
```

```
Content-Length: 40
```

Percona XtraDB Cluster Node is synced.

In case node isn't synced or if it is offline, status will look like:

```
HTTP/1.1 503 Service Unavailable
Content-Type: text/plain
Connection: close
Content-Length: 44
Percona XtraDB Cluster Node is not synced.
```

🧪 Note

The clustercheck script has the following syntax:

<user> <user> <available_when_donor=0|1> <log_file> <available_when_readonly=0|1> <defaults_extra_file>

Recommended: server_args = user pass 1 /var/log/log-file 0 /etc/my.cnf.local

Compatibility: server_args = user pass 1 /var/log/log-file 1 /etc/my.cnf.local

11.6.5 How does Percona XtraDB Cluster handle big transactions?

Percona XtraDB Cluster populates write set in memory before replication, and this sets the limit for the size of transactions that make sense. There are wsrep variables for maximum row count and maximum size of write set to make sure that the server does not run out of memory.

11.6.6 Is it possible to have different table structures on the nodes?

For example, if there are four nodes, with four tables: sessions_a, sessions_b, sessions_c, and sessions_d, and you want each table in a separate node, this is not possible for InnoDB tables. However, it will work for MEMORY tables.

11.6.7 What if a node fails or there is a network issue between nodes?

The quorum mechanism in Percona XtraDB Cluster will decide which nodes can accept traffic and will shut down the nodes that do not belong to the quorum. Later when the failure is fixed, the nodes will need to copy data from the working cluster.

The algorithm for quorum is Dynamic Linear Voting (DLV). The quorum is preserved if (and only if) the sum weight of the nodes in a new component strictly exceeds half that of the preceding Primary Component, minus the nodes which left gracefully.

The mechanism is described in detail in Galera documentation.

11.6.8 How would the quorum mechanism handle split brain?

The quorum mechanism cannot handle split brain. If there is no way to decide on the primary component, Percona XtraDB Cluster has no way to resolve a split brain. The minimal recommendation is to have 3 nodes. However, it is possibile to allow a node to handle traffic with the following option:

```
wsrep_provider_options="pc.ignore_sb = yes"
```

11.6.9 Why a node stops accepting commands if the other one fails in a 2-node setup?

This is expected behavior to prevent split brain. For more information, see previous question or Galera documentation.

11.6.10 Is it possible to set up a cluster without state transfer?

It is possible in two ways:

- 1. By default, Galera reads starting position from a text file <datadir>/grastate.dat. Make this file identical on all nodes, and there will be no state transfer after starting a node.
- 2. Use the wsrep start position variable to start the nodes with the same UUID: seqno value.

11.6.11 What TCP ports are used by Percona XtraDB Cluster?

You may need to open up to four ports if you are using a firewall:

- 1. Regular MySQL port (default is 3306).
- 2. Port for group communication (default is 4567). It can be changed using the following option:

wsrep_provider_options ="gmcast.listen_addr=tcp://0.0.0.0:4010; "

3. Port for State Snaphot Transfer (default is 4444). It can be changed using the following option:

wsrep sst receive address=10.11.12.205:5555

4. Port for Incremental State Transfer (default is port for group communication + 1 or 4568). It can be changed using the following option:

wsrep_provider_options = "ist.recv_addr=10.11.12.206:7777; "

11.6.12 Is there "async" mode or only "sync" commits are supported?

Percona XtraDB Cluster does not support "async" mode, all commits are synchronous on all nodes. To be precise, the commits are "virtually" synchronous, which means that the transaction should pass *certification* on nodes, not physical commit. Certification means a guarantee that the transaction does not have conflicts with other transactions on the corresponding node.

11.6.13 Does it work with regular MySQL replication?

Yes. On the node you are going to use as source, you should enable log-bin and log-slave-update options.

11.6.14 Why the init script (/etc/init.d/mysql) does not start?

Try to disable SELinux with the following command:

echo 0 > /selinux/enforce

11.6.15 What does "nc: invalid option – 'd'" in the sst.err log file mean?

This error is specific to Debian and Ubuntu. Percona XtraDB Cluster uses netcat-openbsd package. This dependency has been fixed. Future releases of Percona XtraDB Cluster will be compatible with any netcat (see bug PXC-941).

Last update: 2023-01-20

11.7 Glossary

11.7.1 .frm

For each table, the server will create a file with the ...frm extension containing the table definition (for all storage engines).

11.7.2 ACID

An acronym for Atomicity, Consistency, Isolation, Durability.

11.7.3 Asynchronous replication

Asynchronous replication is a technique where data is first written to the primary node. After the primary acknowledges the write, the data is written to secondary nodes.

11.7.4 Atomicity

This property guarantees that all updates of a transaction occur in the database or no updates occur. This guarantee also applies with a server exit. If a transaction fails, the entire operation rolls back.

11.7.5 Cluster replication

Normal replication path for cluster members. Can be encrypted (not by default) and unicast or multicast (unicast by default). Runs on tcp port 4567 by default.

11.7.6 Consistency

This property guarantees that each transaction that modifies the database takes it from one consistent state to another. Consistency is implied with Isolation.

11.7.7 datadir

The directory in which the database server stores its databases. Most Linux distribution use /var/lib/mysql by default.

11.7.8 donor node

The node elected to provide a state transfer (SST or IST).

11.7.9 Durability

Once a transaction is committed, it will remain so and is resistant to a server exit.

11.7.10 Foreign Key

A referential constraint between two tables. Example: A purchase order in the purchase_orders table must have been made by a customer that exists in the customers table.

11.7.11 General availability (GA)

A finalized version of the product which is made available to the general public. It is the final stage in the software release cycle.

11.7.12 GTID

Global Transaction ID, in Percona XtraDB Cluster it consists of UUID and an ordinal sequence number which denotes the position of the change in the sequence.

11.7.13 HAProxy

HAProxy is a free, very fast and reliable solution offering high availability, load balancing, and proxying for TCP and HTTP-based applications. It is particularly suited for web sites crawling under very high loads while needing persistence or Layer7 processing. Supporting tens of thousands of connections is clearly realistic with todays hardware. Its mode of operation makes its integration into existing architectures very easy and riskless, while still offering the possibility not to expose fragile web servers to the net.

11.7.14 ibdata

Default prefix for tablespace files, e.g., ibdatal is a 10MB auto-extendable file that *MySQL* creates for the shared tablespace by default.

11.7.15 Isolation

The Isolation guarantee means that no transaction can interfere with another. When transactions access data in a session, they also lock that data to prevent other operations on that data by other transaction.

11.7.16 IST

Incremental State Transfer. Functionality which instead of whole state snapshot can catch up with the group by receiving the missing writesets, but only if the writeset is still in the donor's writeset cache.

11.7.17 InnoDB

Storage Engine for MySQL and derivatives (Percona Server, MariaDB) originally written by Innobase Oy, since acquired by Oracle. It provides ACID compliant storage engine with foreign key support. InnoDB is the default storage engine on all platforms.

11.7.18 Jenkins

Jenkins is a continuous integration system that we use to help ensure the continued quality of the software we produce. It helps us achieve the aims of: * no failed tests in trunk on any platform * aid developers in ensuring merge requests build and test on all platforms * no known performance regressions (without a damn good explanation)

11.7.19 joiner node

The node joining the cluster, usually a state transfer target.

11.7.20 LSN

Log Serial Number. A term used in relation to the InnoDB or XtraDB storage engines. There are System-level LSNs and Page-level LSNs. The System LSN represents the most recent LSN value assigned to page changes. Each InnoDB page contains a Page LSN which is the max LSN for that page for changes that reside on the disk. This LSN is updated when the page is flushed to disk.

11.7.21 MariaDB

A fork of MySQL that is maintained primarily by Monty Program AB. It aims to add features, fix bugs while maintaining 100% backwards compatibility with MySQL.

11.7.22 my.cnf

This file refers to the database server's main configuration file. Most Linux distributions place it as /etc/mysql/my.cnf or /etc/my.cnf, but the location and name depends on the particular installation. Note that this is not the only way of configuring the server, some systems does not have one even and rely on the command options to start the server and its defaults values.

11.7.23 MyISAM

A MySQL Storage Engine that was the default until MySQL 5.5. It doesn't fully support transactions but in some scenarios may be faster than InnoDB. Each table is stored on disk in 3 files: .frm, i .MYD, .MYI.

11.7.24 MySQL

An open source database that has spawned several distributions and forks. MySQL AB was the primary maintainer and distributor until bought by Sun Microsystems, which was then acquired by Oracle. As Oracle owns the MySQL trademark, the term MySQL is often used for the Oracle distribution of MySQL as distinct from the drop-in replacements such as MariabB and Percona Server.

11.7.25 mysql.pxc.internal.session

This user is used by the SST process to run the SQL commands needed for SST, such as creating the mysql.pxc.sst.user and assigning it the role mysql.pxc.sst.role.

11.7.26 mysql.pxc.sst.role

This role has all the privileges needed to run xtrabackup to create a backup on the donor node.

11.7.27 mysql.pxc.sst.user

This user (set up on the donor node) is assigned the <code>mysql.pxc.sst.role</code> and runs the XtraBackup to make backups. The password for this is randomly generated for each SST. The password is generated automatically for each SST.

11.7.28 node

A cluster node - a single mysql instance that is in the cluster.

11.7.29 NUMA

Non-Uniform Memory Access (NUMA) is a computer memory design used in multiprocessing, where the memory access time depends on the memory location relative to a processor. Under NUMA, a processor can access its own local memory faster than non-local memory, that is, memory local to another processor or memory shared between processors. The whole system may still operate as one unit, and all memory is basically accessible from everywhere, but at a potentially higher latency and lower performance.

11.7.30 Percona Server for MySQL

Percona's branch of MySQL with performance and management improvements.

11.7.31 Percona XtraDB Cluster

Percona XtraDB Cluster (PXC) is a high availability solution for MySQL.

11.7.32 primary cluster

A cluster with quorum. A non-primary cluster will not allow any operations and will give Unknown command errors on any clients attempting to read or write from the database.

11.7.33 quorum

A majority (> 50%) of nodes. In the event of a network partition, only the cluster partition that retains a quorum (if any) will remain Primary by default.

11.7.34 split brain

Split brain occurs when two parts of a computer cluster are disconnected, each part believing that the other is no longer running. This problem can lead to data inconsistency.

11.7.35 SST

State Snapshot Transfer is the full copy of data from one node to another. It's used when a new node joins the cluster, it has to transfer data from an existing node. Percona XtraDB Cluster: uses the xtrabackup program for this purpose. xtrabackup does not require READ LOCK for the entire syncing process - only for syncing the MySQL system tables and writing the information about the binlog, galera and replica information (same as the regular Percona XtraBackup backup).

The SST method is configured with the wsrep_sst_method variable.

In PXC 8.0, the **mysql-upgrade** command is now run automatically as part of **SST**. You do not have to run it manually when upgrading your system from an older version.

11.7.36 Storage Engine

A Storage Engine is a piece of software that implements the details of data storage and retrieval for a database system. This term is primarily used within the MySQL ecosystem due to it being the first widely used relational database to have an abstraction layer around storage. It is analogous to a Virtual File System layer in an Operating System. A VFS layer allows an operating system to read and write multiple file systems (for example, FAT, NTFS, XFS, ext3) and a Storage Engine layer allows a database server to access tables stored in different engines (e.g. MyISAM, InnoDB).

11.7.37 Tech preview

A tech preview item can be a feature, a variable, or a value within a variable. The term designates that the item is not yet ready for production use and is not included in support by SLA. A tech preview item is included in a release so that users can provide feedback. The item is either updated and released as general availability(GA) or removed if not useful. The item's functionality can change from tech preview to GA.

11.7.38 UUID

Universally Unique IDentifier which uniquely identifies the state and the sequence of changes node undergoes. 128-bit UUID is a classic DCE UUID Version 1 (based on current time and MAC address). Although in theory this UUID could be generated based on the real MAC-address, in the Galera it is always (without exception) based on the generated pseudo-random addresses ("locally administered" bit in the node address (in the UUID structure) is always equal to unity).

11.9 Trademark policy

This Trademark Policy is to ensure that users of Percona-branded products or services know that what they receive has really been developed, approved, tested and maintained by Percona. Trademarks help to prevent confusion in the marketplace, by distinguishing one company's or person's products and services from another's.

Percona owns a number of marks, including but not limited to Percona, XtraDB, Percona XtraBackup, Percona XtraBackup, Percona Server, and Percona Live, plus the distinctive visual icons and logos associated with these marks. Both the unregistered and registered marks of Percona are protected.

Use of any Percona trademark in the name, URL, or other identifying characteristic of any product, service, website, or other use is not permitted without Percona's written permission with the following three limited exceptions.

First, you may use the appropriate Percona mark when making a nominative fair use reference to a bona fide Percona product.

Second, when Percona has released a product under a version of the GNU General Public License ("GPL"), you may use the appropriate Percona mark when distributing a verbatim copy of that product in accordance with the terms and conditions of the GPL.

Third, you may use the appropriate Percona mark to refer to a distribution of GPL-released Percona software that has been modified with minor changes for the sole purpose of allowing the software to operate on an operating system or hardware platform for which Percona has not yet released the software, provided that those third party changes do not affect the behavior, functionality, features, design or performance of the

software. Users who acquire this Percona-branded software receive substantially exact implementations of the Percona software.

Percona reserves the right to revoke this authorization at any time in its sole discretion. For example, if Percona believes that your modification is beyond the scope of the limited license granted in this Policy or that your use of the Percona mark is detrimental to Percona, Percona will revoke this authorization. Upon revocation, you must immediately cease using the applicable Percona mark. If you do not immediately cease using the Percona mark upon revocation, Percona may take action to protect its rights and interests in the Percona mark. Percona does not grant any license to use any Percona mark for any other modified versions of Percona software; such use will require our prior written permission.

Neither trademark law nor any of the exceptions set forth in this Trademark Policy permit you to truncate, modify or otherwise use any Percona mark as part of your own brand. For example, if XYZ creates a modified version of the Percona Server, XYZ may not brand that modification as "XYZ Percona Server" or "Percona XYZ Server", even if that modification otherwise complies with the third exception noted above.

In all cases, you must comply with applicable law, the underlying license, and this Trademark Policy, as amended from time to time. For instance, any mention of Percona trademarks should include the full trademarked name, with proper spelling and capitalization, along with attribution of ownership to Percona Inc. For example, the full proper name for XtraBackup is Percona XtraBackup. However, it is acceptable to omit the word "Percona" for brevity on the second and subsequent uses, where such omission does not cause confusion.

In the event of doubt as to any of the conditions or exceptions outlined in this Trademark Policy, please contact trademarks@percona.com for assistance and we will do our very best to be helpful.
